In 1941 the Luxmoore Committee was appointed "to examine the present system of agricultural education in England and Wales, and to make recommendations for improving and developing it after the war". The Committee found that technical advice reached the farmer from two separate advisory services, the county service and the provincial service. The county advisory service possessed some men of outstanding ability and personality who with their staffs had given valuable assistance to the farming community especially in periods of depression and also during the war-time campaign to increase food production. The standard of the service, however, varied greatly and tended to be lower in counties where agriculture was the main industry. There were several causes for this: funds for agricultural education were generally smaller in agricultural counties where rateable values were low; local interests were occasionally detrimental to the development of the county advisory service, and in some counties those engaged in the agricultural industry had no sympathy with the science of agriculture and failed to appreciate the value of technical assistance. Occasionally members of the county agricultural service were used for purely administrative duties, and serious under-staffing made it impossible for them to maintain contact with more than a few farmers. The existence and functions of the provincial advisory service were not widely known. Provincial centres were controlled by either a chief advisory officer, a professor of agriculture, or the principal of an agricultural college. There was some lack of co-ordination between the advisory officers of a province, and at agricultural colleges there was little or no contact between the advisory officers and other scientific workers. Accommodation and equipment for advisory officers was frequently unsuitable and inadequate. It had been intended that the two services should co-operate in a relationship closely analogous to that between the general medical practitioner and the medical specialist; and that together the services should link agricultural research with farm practice, the provincial advisers having stronger affinities with research and the county staffs with practice. Co-operation was unorganized and in consequence varied greatly in different counties and provinces. In many cases the county advisory service had failed to make sufficient use of the provincial advisory service either because the county organizer did not recognize the problems calling for specialist advice or because the county service had become self-sufficient by the appointment of specialists to its

staff. In other cases provincial advisers had tended to usurp the functions of county organizers, or they were not sufficiently acquainted with agriculture to gain the confidence of practical men. Thus instead of a steady stream of ideas from the research institutes reaching the farmer through the provincial and county services as intended, the groups of workers associated with agriculture were linked loosely and haphazardly and, in some cases, not linked at all.

The Luxmoore Committee recognized the necessity for the continuation, improvement and extension of the agricultural advisory services and suggested that county and provincial services be combined into a national service. The aim of the proposed national advisory service would be to give every farmer easy access to the best practical and scientific information available. To achieve this the Committee suggested that each county should be divided into districts, their size to be determined either by the number of farmers or by the acreage of agricultural land. Each district should have a district officer whose duty would be to advise and help the farmers in his area. He should visit all the farms in his district at least once a year, arrange for meetings of farmers, demonstrations, lectures and discussions. A county organizer would direct and co-ordinate the work of the district officers, advise on local problems and where necessary forward them to specialist officers. In addition, the county organizer would have a staff of assistants qualified to give instruction and advice on such subjects as dairying, poultry-keeping, and the maintenance and repair of farm machinery. The specialist advisory service should be continued on a provincial basis, but in order to provide for a more comprehensive range of agricultural sciences it was suggested that the number of provinces should be reduced from thirteen to six and the staff appropriately increased. Specialist advisory officers should be scientific men with some practical experience of agriculture, and they should be allowed the freedom on which original thought and successful investigation depend. The co-ordination of the work of the specialist staff at the centre should be the responsibility of a chief advisory officer who should not himself be called upon to do advisory work. There should also be a provincial organizer to co-ordinate the work of the county organizers and their staffs throughout the province. A provincial administrator should be administrative head of both branches of the service and responsible for the office organization of the province.

The Association of Applied Biologists has many links with the advisory and research services in agriculture, and though members were agreed that the advisory services needed overhauling and re-organization, the proposals of the Luxmoore Committee received critical examination. An outstanding omission was lack of proposals for the co-ordination and integration of advisory and research services. It was obvious that the Luxmoore Committee was hampered by terms of reference that excluded the research service from the inquiry. The advisory and research services were essentially interdependent and the work of each provided stimulus to the other. The Luxmoore proposals would tend to isolate the two services and sever established relationships. The removal of specialist advisers from the university departments would isolate them from scientific contacts, and the transfer of advisory centres from the universities would lower the status of the specialists and weaken their ties with other scientific workers.

The provision of specialist advisers on a scientific basis was commented on, and it was suggested that recent developments in the sciences associated with agriculture necessitated widening the scope of the advisory services. Besides the advisers in entomology, mycology, chemistry, economics and veterinary science, there was need for advisers in such subjects as plant physiology, animal nutrition, virology, microbiology, helminthology. The Luxmoore proposals provided for advisers for all kinds of husbandry at the county level, and if suitably trained and experienced advisers were selected there should be no need for further specialist husbandry officers. Although the number of provincial centres would be reduced by the Luxmoore proposals, increases in personnel were suggested, and it should be possible to arrange that all branches of the agricultural sciences were represented. The provincial outstations, which were an integral part of the suggested provincial organization, might well be used as centres for additional specialists whose services would be available for the province. The enlarged provinces should offer better facilities for the training of new entrants to the specialist advisory service. The concentration of the specialist service at six provincial centres should make it possible to provide adequate accommodation and the necessary equipment of staff and apparatus for laboratory and field investigations. The advisory services had in the past been hampered by unsuitable accommodation and lack of facilities for their work.

It was noted that the organization of the advisory services as suggested by the Luxmoore Committee made no provision for the co-ordination of the work of specialist advisers in the particular sciences. The province would be a self-contained unit with no organized contacts beyond its boundaries. It was of great importance to all types of advisers that they should maintain contacts with advisers faced with similar problems in other provinces. Many of the major agricultural problems occurred in similar or related forms in several provinces, and interchange of experience, co-ordination of advisory and investigational work and arrangement of co-operative experiments should be possible. At present co-ordination of the work of entomologists and mycologists was achieved through the Plant Pathological Laboratory of the Ministry of Agriculture. Co-ordination of specialist investigations and advisory work might be obtained under the Luxmoore proposals if chief advisory officers were representative of various agricultural sciences and were charged with the responsibility of co-ordinating on a national scale the work in their respective sciences, in addition to co-ordinating the specialist work within their provinces.

Mr. Ronald Ede, secretary of the Luxmoore Committee, explained to the Association the permissive character of the present system of agricultural education and that the total expenditure of £600,000 for 1938–39 for all agricultural education and technical advice was quite inadequate for the needs of a basic industry like agriculture, the products of which were valued at £250 millions a year. The present county advisory system offered little chance of promotion and advancement except within the county and did not provide sufficient incentive for progressive young men. The establishment of a national advisory service would obviate some of the disadvantages occurring from the number and variety of responsible authorities, and its dependence on the national exchequer would ensure that all counties were served according to their needs and not according to their

financial resources. The proposed reduction in the number of provincial centres should allow greater numbers of specialists at each centre, and the development of out-stations of the provincial service should ensure that no part of the country was isolated from specialist assistance and that areas with special and distinctive needs would have necessary assistance. The provincial centres were to be established in university towns, though they would not be administered by the universities. The case for the integration of the existing advisory services into a comprehensive national service was strong. The agricultural industry would be better served by an organized and coordinated service, and greater opportunities for promotion and improved professional status would ensure that capable and energetic men entered the service.

OBITUARIES

Lieut.-Colonel Stanley Casson

BORN in 1889, Stanley Casson went from Merchant Taylors School to Lincoln College, Oxford, and held a senior scholarship at St. John's and a studentship at the British School of Archæology at Athens. In 1914 the War interrupted his studies, but he made good use of local opportunities in Macedonia and returned thither for excavation after the Armistice. During 1919–22 he was assistant-director of the School, and was elected in 1920 to a fellowship of New College, which combined opportunity for travel and research with a limited amount of lecturing under Prof. Percy Gardner, to whose philosophic outlook he owed much.

In 1924, Casson's historical geography of "Macedonia, Thrace and Illyria" won the Conington Prize, and after its publication in 1929 he produced a series of studies of Greek and modern sculpture—"The Technique of Early Greek Sculpture", "Some Modern Sculptors", "Twentieth Century Sculpture, and Artists at Work"—the result of much thought, observation and experiment in technique and equipment. In 1927 he was promoted to a university lectureship, and in 1928 he was proctor. In 1929 he explored the Hippodrome at Constantinople for the British Academy. In later years he gave much time to organized visits of younger students to Greece, and to more general and popular writings, "The Progress of Archæology" (1935), "The Discovery of Mars" (1939) and "Progress and Catastrophe" (1937), the last a remarkable anticipation of present disasters. He wrote also reminiscences of war service, a detective story, a volume of essays on "Ancient Cyprus" (1937), and in 1939–43 valuable summaries of the history and services of the Greeks, "Greece and Britain", "Greece and the Axis" and a re-issue of his "Ancient Greece". He was a fellow of the Society of Antiquaries, honorary associate of the Royal Institute of British Architects, member of the German Archæological Institute and honorary member of the Bulgarian Archæological Institute. In 1939 he rejoined the Intelligence Corps, served in the Netherlands and in Greece, and was again on active service when he was killed in April 1944. He leaves a wife and one daughter.

Casson was a devoted and effective exponent of Greek antiquity, in all aspects and periods, especially of the sculpture and its counterparts in modern Europe. He had also exceptionally wide knowledge of the modern Greek people, among whom he was widely known and very popular. JOHN L. MYRES.

Mr. L. V. Lester-Garland

LESTER VALLIS LESTER-GARLAND (*olim* Lester), who died on March 23, was of the scholarly type of botanist more common in former days. Born on July 28, 1860, he was educated at Sherborne School and at Magdalen College, Oxford, where he held a demyship. He took a first in classical moderations and in 'Greats'. After being an assistant master at St. Edward's School, Oxford, during 1883–86, he became fellow and lecturer at St. John's College, Oxford, where he remained for ten years. In 1896 he became president of Victoria College, Jersey, retiring in 1911.

Lester-Garland is best known botanically for his "Flora of the Island of Jersey", published in 1903. This small volume is a model of what a local Flora should be. Incidentally, it was the first British Flora to adopt the Engler system of classification. In the introduction he asserts that if British botanists "are ever to emancipate themselves from the insular ideas which too often dominate the science, they will have to learn to look abroad, and realize that British plants grow in other places besides Great Britain and Ireland, and that the British flora is only an insignificant portion of the flora of the globe". The need was probably brought home to him by the continental affinities of the Jersey flora, with its conspicuous Mediterranean element; it led him to criticize the continued use of Watson's 'types' as tending to limit the views of British botanists on plant distribution.

His only other botanical publications were short papers, but for some time after leaving Jersey he was prominent in London botanical circles, and served on the council of the Linnean Society during 1923–26. On moving to Bathford he busied himself with local affairs and restricted his writings to religious philosophy.

Lester-Garland had a charming and unassuming manner which covered not only a wise, scholarly knowledge but also a sense of humour and convictions which were strongly, but not stupidly, held.

J. RAMSBOTTOM.

Dr. A. R. Jackson

WITH the death of Dr. A. Randall Jackson at his home in Chester on March 18 we lose our leading British systematic arachnologist. Despite a busy medical practice, he always found time to provide unstinted help to numerous correspondents in the identification of their collections of British and Arctic spiders, phalangids and chelonethids. This flair for diagnosis has never been surpassed. It enabled him both to straighten out the synonymic muddles created by other workers and also to add many species to the British list. Despite the constant pleadings of his friends, he published comparatively few papers and, as these were often in obscure journals, the excellence of his work never gained the wide recognition it deserved.

A rugged exterior concealed a sensitive and sentimental nature with a deep interest in the beauty of good literature, paintings and garden flowers. A manner, at times somewhat cynical, was apt to hide a keen sense of humour, conscientious attention to his medical practice and, above all, the kindness and generosity he always showed to young collectors. His death is a serious loss to British arachnology.

W. S. BRISTOWE.

NEWS and VIEWS

Mr. G. Shaw Scott and the Institute of Metals

THE first decade of the twentieth century produced a number of explorers keen to discover in the science of metals the most efficient and economic ways to adapt 'brass and iron' to the service of man. Papers published at the time were concerned with the microstructures of metals and alloys, and the influence of the nature and distribution of micro-constituents on mechanical properties. Hence there arose a need for the results of such work to be published among manufacturers and users of metal, while scientific men required a fellowship for mutual help and criticism. The Institute of Metals was founded to meet these needs in September 1908, its temporary headquarters being the Department of Metallurgy of the University of Birmingham. The first secretary was Mr. Gilbert Shaw Scott, who is now retiring after thirty-two years of service.

In 1906, Mr. Shaw Scott graduated at the University of Birmingham as its first graduate in metallurgy, and was the first research student in the Department. In 1908 he read a paper on case hardening to the Iron and Steel Institute at its meeting in Vienna. From a large number of candidates, he was chosen to be the first secretary of the new Institute, and under his guidance it has grown from its original membership of 250 to a present world-wide membership of 2,500. Examples of scientific and technical progress with which he has been associated as secretary and editor to the Institute of Metals include the new knowledge of metallic crystals, equilibrium diagrams and micro-constituents of metals and alloys, the industrial use of microscope and pyrometer as instruments for the control of quantity and quality; the discovery and development of modern alloys of aluminium; the discovery of a copper alloy which can be hardened and tempered by heat treatment; the winning battle against corrosion, and bright annealing. Since 1908, his services to the members of the Institute of Metals have been to make available the new knowledge so necessary to the metallurgical industries. His friends will remember gratefully the prompt help and genial advice always received, and wish him on retirement many happy days.

Charles L. Mayer Prize of the U.S. National Science Fund: Dr. Alexander Lipschütz

DR. ALEXANDER LIPSCHÜTZ, director of the Department of Experimental Medicine of the Chilean National Health Service at Santiago, Chile, has been awarded the second 2,000 dollars prize given by Dr. Charles L. Mayer and administered by the National Science Fund of the U.S. National Academy of Sciences. The award was offered for an outstanding contribution made in 1943 to present-day knowledge of factors affecting the growth of animal cells with particular reference to human cancer. Dr. Lipschütz was born in Riga, where he received his early education. He occupied various positions in medicine and physiology at institutions in Switzerland and Germany before going to Chile about fifteen years ago to work at the Catholic University at Concepcion. Since 1938 he has been director of the Department of Experimental Medicine of the National Health Service at Santiago, Chile. Throughout the past six years Dr. Lipschütz, with Chilean collaborators, has studied the fibromyomas of the uterus which can be induced in guinea pigs by the injection of certain sex hormones of the female. The growths closely resemble the fibromyomas ('fibroids') which occur in women during the childbearing period, and Dr. Lipschütz has shown that, like these, they dwindle and vanish when the stimulation of the sex hormones is withdrawn, as happens after the menopause in women. He and his associates have sought means to prevent the occurrence and enlargement of the growths while the hormones are still acting, and recently they have found that some other hormones have this effect, as do also certain synthetic substances. The molecular configurations responsible for the influence of the antifibromatogenic agents are now under investigation; a progress report by Dr. Lipschütz was published in NATURE of February 26, 1944, p. 260.

Award for Production of Magnesium and Calcium

MR. G. D. BAGLEY, leader of the experimental engineering group of the Union Carbide and Carbon Research Division, has been awarded the Jacob F. Schoellkopf Medal for 1944 by the Western New York Section of the American Chemical Society, for "outstanding and highly significant work, particularly in the fields of the commercialization of very active metals". Largely through his chemical and engineering skill, a process has been developed which produces magnesium in high-temperature vacuum furnaces with capacities which were formerly thought to be impossible. Previously, the dolomite-ferrosilicon reaction for making metallic magnesium had always been considered a laboratory curiosity. Mr. Bagley's production methods are being carried out at the Electro Metallurgical Company's plant at Spokane, Washington, with a rated capacity of 24,000 tons a year. Mr. Bagley has also developed a method for the production of metallic calcium. Before the War, calcium came almost exclusively from France and was made in small cells at a high production cost. When this source was cut off, Mr. Bagley designed large automatic cells, which are now producing a purer product at a considerably reduced cost. Mr. Bagley, who has been with the Union Carbide and Carbon Research Laboratories since 1918, has also been wholly or partially responsible for many other highly important chemical and chemical engineering developments.

Federation of British Industries: Industrial Research Committee

THE Federation of British Industries has decided to strengthen its organization on the research side by making its Industrial Research Committee a permanent standing committee of the Federation, with its own secretariat. By its terms of reference this Committee will seek to stimulate national interest in research for industry and foster it in all appropriate ways. Thus it will encourage industrialists to devote a more adequate part of their resources to the promotion of research and its application to existing products and to the development of new products. It will provide money for the creation and maintenance of adequate facilities for postgraduate research; and encourage the education of the necessary research and development staff of universities, technical colleges and industrial establishments. The

Committee will promote contact and collaboration wherever possible between centres of industrial research or institutions and research workers; and facilitate co-operative research within British industry, with special reference to the needs of small-scale industries. Information on research questions will be provided by creating a liaison with appropriate reference libraries and technical and scientific institutions; and attention directed to the publications of professional, technical and scientific institutions, assistance being given where necessary in their distribution. The Committee will promote the compilation of general information on industrial research, particulars of organizations and the facilities available; and provide from time to time information for press and public on the achievements of British industrial research.

A Medical Nobel Institute in Sweden

The Royal Caroline Institute (Kungl. Karolinska Medico-Kirurgiska Institutet), which is the medical school of Stockholm—the University of Stockholm (Stockholms Högskola) having no medical faculty—and is in charge of the medical Nobel Fund, has decided to build a Medical Nobel Institute for research in the three theoretical disciplines, anatomy, biochemistry and physiology. The new Institute will consist of three departments in one building to be erected on the premises of the new medical centre at Norrbacka in the north-west region of the city. The Biochemical Nobel Institute was founded in 1937 and is directed by Prof. Hugo Theorell. The physiological department will be a Neurophysiological Research Laboratory privately endowed in 1940 for Prof. Ragnar Granit, who will also be in charge of the new institute. The anatomical department will be associated with a new chair in cell research to be created for Dr. Torbjörn Caspersson.

Relation of Employment to an Economic System

A memorandum "Employment After the War" submitted by the Social Credit Co-ordinating Committee, Greno House, Swinton, Mexborough, Yorks (3*d.*), for the consideration of Sir William Beveridge, argues that full employment is not the right objective of an efficient economic system. The essential function of industry is to supply the goods and services which people require, and it is no part of the function of industry to deprive people of leisure or to keep them occupied in order to reduce the difficulties of Government. Social security, with freedom, can only be realized if we recognize, first, that production is no longer a major problem: the problem to-day is that of distributing the abundance of goods that can be produced. Further, money is the social mechanism for the distribution of goods: thirdly, science has so well succeeded in harnessing solar energy to the service of man that the need for human labour in industry has decreased and will continue to decrease progressively; and, lastly, the true purpose of employment is to provide goods and services for our use and not to provide people with incomes. The memorandum then briefly summarizes the Social Credit proposals: a national credit office; the institution of a scientific price discount; and the distribution of national dividends. These proposals are designed to deal with what is described as the real problem, which is not how to share out the hours of work available, but how to remove from unemployment its ugly concomitants of frustration and a low standard of living.

Institute of Medical Laboratory Technology

The Institute of Medical Laboratory Technology, which was incorporated in November 1942, with registered offices at 308 Dewsbury Road, Wakefield, Yorks, has issued a memorandum and articles of association. All scientific workers will commend the objects of this Institute. As its secretary, Mr. S. J. Denyer, says, its formation "indicates the desire of the laboratory technician to meet the increased demands of his profession and to acquire the professional status already accorded to other scientific workers". The Institute incorporates the Pathological and Bacteriological Laboratory Assistants Association and takes over the publication of the *Laboratory Journal* and the *Monthly Bulletin* previously issued by that Association. To meet modern demands, the Institute requires an approved educational standard as one qualification for membership. Ordinary members or associates of the Pathological and Bacteriological Laboratory Assistants Association may become ordinary members of the Institute by application, but others must be elected; they must be not less than twenty years old, they must have had not less than three years experience in an approved pathological, bacteriological or chemical pathology laboratory and must pass an intermediate examination controlled by the Institute. Candidates for the associateship of the Institute must either hold the certificate of the parent Association in one subject or must, after completing five years training in an approved laboratory and attaining the age of twenty-two, pass the Institute's final examination in one subject. Fellows must have been registered members of the parent Association for ten or more years, or must hold that Association's certificates in two or more subjects; in either case they can become fellows by application. Others may be elected to fellowship if they are already associates of the Institute and either pass the Institute's final examination in two or more subjects or submit an acceptable thesis, and have also been associates of the Institute for ten or more years, inclusive of previous registered membership of the parent Association.

It will be clear that the associateship and the fellowship of the new Institute are not lightly acquired, and ordinary membership must itself command respect. This will give to the technicians in the laboratories concerned the status which they deserve, for without their willing help, their interest in the work and their devotion to it, many great discoveries would not have been made. It is good to know that members of the medical profession give willingly of their time to help to train these essential workers; every other kind of scientific worker will wish to do the same.

Smithsonian Institution: Annual Report

The report of the Smithsonian Institution for the year ended June 30, 1942 (Washington, D.C.: Gov. Printing Office. 1.50 dollars), includes the report of the secretary together with the reports on the United States National Museum, the Bureau of American Ethnology, the International Exchange Service, the National Zoological Park, the Astrophysical Observatory, and the Division of Radiation and Organisms, together with a general appendix on the lines of that in the previous report. Referring to the war activities of the Institution, the secretary's report states that a War Committee has been constituted and a detailed roster prepared of the scientific staff, numbering

nearly a hundred, listing their geographical and specialized knowledge. From war agencies 460 requests for information have been received since the Pearl Harbour disaster, and the Institution is also serving as an important source of technical and geographical information. Together with the National Research Council, the American Council of Learned Societies, and the Social Science Research Council, the Institution has participated in the setting up of the Ethnogeographic Board to provide a central clearing house for information to army and navy intelligence and other war agencies in geography, languages and social sciences. An index of published photographs taken by scientific workers of the Institution in all parts of the world is being compiled.

The Institution has also undertaken the publication of a handbook of the Indians of South America, under the editorship of Dr. J. H. Seward, of the Bureau of American Ethnology, as well as of a list of the insects of South and Central America. Volume 6 of the *Annals of the Astrophysical Observatory*, covering its operations from 1920 to 1939, was published during the year and describes in detail the research on the variation of the sun's radiation. The Division of Radiation and Organisms, which was incorporated during the year as a branch of the Observatory, has continued its work on photosynthesis, plant growth and radiation, and the development of apparatus and methods. Experiments were continued on the factors that influence the changes in rates of respiration of plants, and work is in progress on the isolation and separation of two pigments that occur in dark-grown oat seedlings. The general appendix includes in the first place a statement "The 1914 Tests of the Langley 'Aerodrome' ", by C. G. Abbot, which terminates the controversy between Dr. Orville Wright and the Institution. Among the original and unpublished papers in this appendix are those by J. A. Fleming on "The Sun and the Earth's Magnetic Field", E. P. Henderson and S. N. Perry on "Meteorites and their Metallic Constituents", and C. M. Packard on "Insect Enemies of our Cereal Crops".

Copper Conductors for Overhead Lines

IN a paper read by Messrs. G. W. Preston and H. G. Taylor in London on April 12 before the Institution of Electrical Engineers, the creep of copper conductors and their initial non-elastic extension are considered in relation to their effect on sags and their compensation by an increase in erection tension as an alternative to pre-stressing. Information is given on the annealing characteristics of hard-drawn copper and copper-alloy conductors, with special reference to the effect of impurities in the metal, and maximum safe operating temperatures for such conductors are discussed, together with maximum permissible current loadings. Hollow copper conductors of various types for super-voltage lines are described, and the features of cadmium-copper conductors are dealt with in comparison with other types of high-tensile overhead conductor. Steel-reinforced copper conductors receive special attention, particularly in regard to the protection from corrosion of the steel wires, and results of a long-time investigation are given in full, with conclusions and recommendations. Copper-clad steel wires, their characteristics and use as reinforcement in copper conductors are discussed. Details are given of developments in the application of compressed sleeve joints to copper and copper-alloy conductors, and suitable joints for cadmium-copper and steel-cored copper conductors are described and test results given.

New Products from Cellulose

ACCORDING to an annotation in the January issue of the *Anglo-Swedish Review*, the Swedish Cellulose Co. recently put on the market a wood-pulp product named 'Cellufix'; its manufacture requires the use of alkali, chlorine and alcohol, all of which are produced in Sweden. It is viscous, soluble in water at any temperature and so highly concentrated that a 3 per cent solution will yield a consistency equal to butter. It is odourless and tasteless, and its present main use is as wall-paper paste, as putty and for part of white-wash. 'Cellufix' is also used in textile mills as size and for other purposes. A specially purified quality of 'Cellufix' called 'Cellugel' is used in the food and chemical industries to give bulk to certain products and is also used as a substitute for glycerine.

Planetaria of the World

MR. ROY K. MARSHALL continues his articles on this subject in the December and January issues of *Sky and Telescope* (see NATURE, **153**, 191; Feb. 12, 1944) with a very full description of the Fels Planetarium at the Franklin Institute, Philadelphia. He includes a few photographs of other planetaria also. The technical details of the instrument will prove interesting to many readers. The most complicated feature of the planetarium is the mechanism which reproduces the motions of the sun, moon and planets, and it is remarkable that comparatively few visitors make any inquiries about this. Five projectors are in the sun cage, and two of these are for a glow of light or aureole around the sun's image, simulating the strong scattering of light seen in the neighbourhood of the sun. One is for the zodiacal light, and a pair for the glow of the gegenschein. The precession of the equinoxes is reproduced in the planetarium by rotating the dumbbell portion of the instrument about an axis, and in 75 seconds it is possible to pass through the whole cycle of nearly 26,000 years. On certain occasions demonstrations of a highly dramatic nature have been presented—including a trip to the moon during which very realistic reproductions of lunar craters are produced. In the words of Dr. Philip Fox, describing the first Adler Planetarium, it is "not a trivial plaything, a mimic aping firmament, but the heavens portrayed in great dignity and splendour, dynamic, inspiring, in a way that dispels the mystery but retains the majesty".

Rainfall in the Nile Basin

A SYNOPSIS of rainfall statistics for the Nile Basin up to 1937 forms a valuable volume ("The Nile Basin", 6. By H. E. Hurst and R. P. Black. Physical Dept. Paper No. 43. Ministry of Public Works, Egypt. Cairo, 1943. 10*s*.). It includes figures from the Sudan, Uganda, Kenya, Tanganyika and the Belgian Congo. There are also figures, though admittedly incomplete, from Abyssinia. The stations are grouped by countries, and within each group are arranged by latitude from north to south. Statistics just outside the limits of the Nile basin are included. As a rule, stations with less than five years records are omitted. Figures from about four hundred stations make it possible to give a large-scale map of the total annual rainfall

of the basin, and there are also graphs of the normal monthly rainfall and number of rainy days for selected stations in addition to the lists of these facts for each station where available. The volume concludes with a bibliography and a detailed index to stations.

Public Health in Costa Rica

THE March issue of the *Boletín de la Oficina Sanitaria Panamericana* contains an article on this subject by the President, Dr. Rafael A. Calderón Guardia. The following details are of interest. The birth-rate for 1941 was 42·9 (slight increase) and the death-rate 17 per 1,000. The death-rate for children under one year fell from 132·4 per 1,000 in 1940 to 123·5 in 1941. The services for pre-school and school children have been extended, 11,074 children having been attended by medical men and 18,130 by dentists. During 1941 a section was formed to provide shoes for school children, one of the most important measures for protection of their health. For the first time a travelling exhibition for health education was started and circulated throughout the country. The Tuberculosis Division continued its work of systematic examination of the employees of the various divisions of the department of public health. Of 24,322 persons examined for venereal diseases, 4,242 were found to be infected and 1,305 were classified as doubtful. Soil sanitation was carried out intensively. The anti-malarial campaign was carried on according to the plans of the Rockefeller Foundation. New buildings have been constructed for health units in different parts of the country.

Undulant Fever in Chile

IN a recent article (*Bol. Of. San. Panamericana*, 22, 400 ; 1943) Enrique Onetto, director of the Diagnostic Laboratory of the Chile Bacteriological Institute, discusses the historical aspects and present state of undulant fever in Chile. The disease was first diagnosed in that country in 1931, when it was found near Santiago, and in 1940 a new focus was discovered in the northern part of the country. The commonest variety is *Brucella melitensis*, though *Br. abortus* has also been isolated in cattle. The infection is most prevalent in the southern part of Chile. Since 1936 the Huddleson reaction has been performed systematically on all the sera received for the Widal reaction. In 1936 also the Department of Public Health created a permanent commission for the study of brucellosis composed of medical men, bacteriologists and veterinarians.

Rudolf Boehm (1844–1926)

PROF. RUDOLF BOEHM, a prominent pharmacologist, was born on May 19, 1844, at Nördlingen in Bavaria, the son of a medical man. He received his medical education at Munich, Würzburg and Leipzig, where he qualified in 1867. He first devoted himself to psychiatry, serving as assistant in the psychiatric clinic at Würzburg. Afterwards he took up the study of pharmacology at Leipzig and commenced his important studies on cardiac poisons. In 1871 he was appointed assistant at the Physiological Institute at Würzburg under A. Fick, and in the following year succeeded Schmiedeberg in the chair of pharmacology at Dorpat, eventually holding the corresponding chairs at Marburg and Leipzig. He died on August 16, 1926, in Upper Bavaria. Besides numerous pharmacological articles on veratrin, aconitin, arsenic, digitalis, and curare, and physiological investigations, especially on carbohydrate metabolism, he was the author of a "Lehrbuch der allgemeinen und speziellen Arzneiverordnungslehre" in 1884, the third edition appearing in 1903.

Announcements

SIR LEWIS FERMOR, formerly director of the Geological Survey of India, has been awarded the P. N. Bose Memorial Medal for 1943 of the Royal Asiatic Society of Bengal, in recognition of his "conspicuously important researches on the Archæan Rocks of India".

PROF. C. M. YONGE, professor of zoology in the University of Bristol, has been appointed regius professor in the University of Glasgow, in succession to Prof. E. Hindle, who has become scientific director of the Zoological Society of London.

THE Rockefeller Foundation has made a grant of 15,000 rupees (about £1,100) to the National Institute of Sciences of India, to give assistance in the publication of scientific papers in Indian journals. This grant is similar in character to that which has been made by the Foundation to the Royal Society annually for some years, for assisting the publication of scientific papers in Great Britain.

THE following appointments in the Colonial Service have recently been made: O. J. Voelcker (senior botanist, Nigeria), seconded to Gold Coast for duty in connexion with cocoa diseases; D. Stevenson (senior assistant conservator of forests, Gold Coast), conservator of forests, Gold Coast; J. A. Wills (senior assistant conservator of forests, Gold Coast), conservator of forests, Gold Coast; C. M. Tattam (senior geologist, Nigeria), deputy director of geological surveys, Nigeria.

BY arrangement with the University of Cambridge, the Medical Research Council has established a Unit for Research in Applied Psychology at Cambridge. The Unit is located in the University Psychological Laboratory, the head of which is Prof. F. C. Bartlett. Dr. K. J. W. Craik has been appointed to the Council's staff as director of the Unit, and will have the collaboration or assistance of other workers there in the Council's service. The members of the Unit will undertake work elsewhere than at Cambridge when required, including investigations within the field of the Council's Industrial Health Research Board.

THE Institution of Chemical Engineers and the Institute of Physics announce a joint conference on "Instruments for the Automatic Controlling and Recording of Chemical and Other Processes". Provisional arrangements have been made for the conference to take place in London on September 22 and 23. The purpose of the conference is to promote the interchange of knowledge and experience between those employing automatic controllers and recorders in different fields and to encourage collaboration between physicists and chemical engineers. The conference will be open to all interested without charge. Further particulars will be sent, in August, to those sending a request for them to the Organizing Secretary, Joint Conference, c/o The Institution of Chemical Engineers, 56 Victoria Street, London, S.W.1.

Physico-Chemical Properties of the Surface of Growing Plant Cells

FROM measurements of the surface potential of growing roots of wheat seedlings, it was concluded that the protoplasmic membrane behaves as an amphoteric colloid with pronounced acid dissociation[1]. The protoplasmic membrane probably contains small amounts of a comparatively strong high-molecular acid (pK = c. 1) and still smaller amounts of a comparatively weak base. The main substance of the membrane is apparently not dissociated. The hypothetical acid (R^-) reacts with neutral salts according to the equation $H^+R^- + M^+A^- = M^+R^- + H^+A^-$, following the law of mass action[2]. The acid constituent of the protoplasmic membrane was supposed to be a phosphoric acid in organic linkage.

Earlier spectrochemical investigations of nutrient solutions, in which roots had grown for some time[3], revealed the presence of organic compounds with high absorption in the ultra-violet. These compounds, which are apparently exuded from living cells, contained phosphoric acid and were provisionally identified with phosphatides. Later potential measurements showed, on the other hand, that the presence of phosphatides in the protoplasmic membrane of the growing cells of roots is less probable. A renewed spectrographical and chemical investigation of the root exudates was therefore attempted.

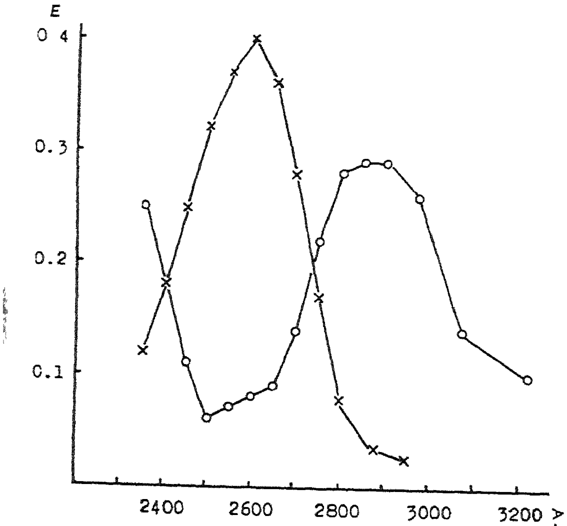

FIG. 1.

The exuded substances are always of the same kind, irrespective of the pH of the solution. Generally, however, the concentration of the exudate increases with the acidity of the medium in which the living wheat roots are submersed. The best medium is distilled water, in which exudates of comparatively high concentration are obtained. The fresh solution of the exudate gives a spectrum with a high absorption maximum extinction at c. 2600 A. and a lower maximum at c. 2850 A. (Fig. 1). The former coincides

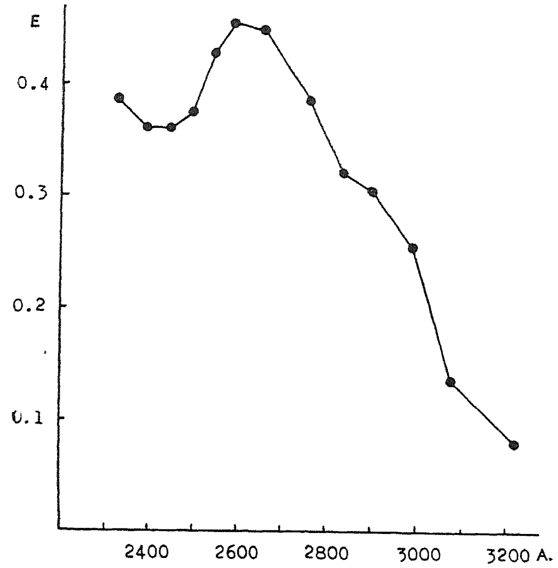

FIG. 2.

with the absorption maximum of purine bases, characteristic of nucleotides. From the known molar extinction of adenylic acid, the probable amount of nucleotide was calculated. A microchemical determination of pentoses in the exudate gave similar values. Furthermore, the amount of PO_4 in organic linkage corresponds to 1–3 moles per mole nucleotide. The substance causing the strong absorption at 2600 A. is therefore probably adenosine phosphoric acid (1–3 PO_4).

On subtracting the spectrum of the supposed adenosine phosphoric acid from the 'raw' spectrum in Fig. 1 we obtain a spectrum with a high peak at c. 2550 A. (Fig. 2). The exudate developed a faint yellow colour in the presence of alkali. After the addition of basic lead acetate a distinct yellow colour appeared, which turned wine-red after the addition of sulphuric acid in excess. These colour reactions are characteristic of dyes belonging to the flavone group. The absorption band at 2550 A. corresponds to the spectrum of flavanone[4]. This substance also gives no absorption between 3200 and 4000 A. The absorption of the lead compound of the dye in the visible part of the spectrum (c. 4700 A.) corresponds to the absorption in the ultra-violet; the second substance in the exudate is therefore probably a flavanone. According to earlier biochemical investigations[5], only flavones with two hydroxyl groups in ortho-positions on the phenyl group are able to participate as oxidizing links in a system consisting of peroxidase and ascorbic acid. On testing our exudate with a mixture of ascorbic acid, hydrogen peroxide and peroxidase, we actually obtained an obvious acceleration of the decomposition of the ascorbic acid. The substance in the exudate causing the absorption band at 2850 A. is thus probably a 3′,4′-dioxyflavanone. Proteins which have an absorption band at a similar wavelength are not present in the exudate.

The fact that nucleotides are exuded from living roots supports the conclusion that these substances are constituents of the protoplasmic membrane of epidermis cells. Root tips (5 mm.) exude per unit dry weight 2–4 times as much nucleotide as the rest of the root. The zone of fastest elongation of the cells (about 2 mm. from the vegetative point) shows

the highest electro-negative potential[6] and the carriers of the potential are perhaps nucleotide molecules, which are scattered in a non-dissociated ground substance of the membrane and from time to time are thrown off from it. New molecules are probably continuously added from the interior of the growing cell, which always contains much nucleic acid[7]. The adenosine phosphoric acid in the protoplasmic membrane of growing cells is perhaps part of a system building up the cellulose wall.

If nucleotides serve as formative bricks in the protoplasmic membrane of growing cells, the permeability of these cells ought to be rather different from that of fully grown cells, which are supposed to be coated with a neutral membrane of more or less lipoid character. Unpublished observations in this laboratory show that growing root hairs admit substances through the protoplasm which are held back by fully grown cells. The exudate in distilled water always contains large amounts (60–70 per cent or more) of glucose. The protoplasmic membrane of growing cells obviously has larger pores than that of fully grown cells. The molecules of the flavanone (molecular weight *c.* 288) possibly permeate from the interior of the cells, but they perhaps also form part of an oxidation system in the protoplasm, for example, in linkage to the adenosine phosphate or as glucosides. The fact that acid reaction of the medium increases the exudation makes it probable that nucleotides are split off from the protoplasmic membrane by hydrolysis. The production of nucleic acids decreases or ceases completely after the end of the nuclear division and, if the hydrolysis continues during the ageing of the cells, the protoplasmic membrane will finally be free from nucleotides and acquire the well-known restrictive permeability of fully grown cells.

Growth-Factors Required for the Nutrition of *Lactobacillus casei* ε

AFTER allowing for the effect of all the then known vitamins of the B complex, investigations by Macrae *et al.*[1] established the presence of another rat growth-factor (factor β) in the amyl alcohol insoluble fraction of acidified liver concentrates. It was shown in Leeds that this factor was essential for the growth of *C. diphtheriæ* (types *intermedius* and *gravis*), and further work on the factor demonstrated its necessity for the growth of *L. casei* (cf. Chattaway *et al.*[2]) and its non-identity with aneurin, riboflavin, pyridoxine hydrochloride, nicotinic acid, choline hydrochloride, calcium pantothenate, inositol and biotin.

Later experiments indicated that the growth-factor requirements of *C. diphtheriæ* differed from those of *L. casei*, the latter appearing the more complex, thus suggesting that these amyl alcohol insoluble concentrates contained more than one active component. The factor required for the nutrition of *C. diphtheriæ* has been described more fully in a paper by Chattaway, Happold and Sandford[3]. The following is a brief summary of the work so far done in these laboratories on the factors necessary for the aerobic growth of *L. casei* ε.

Three factors have so far been indicated: Factor 1, the growth-factor required also by *C. diphtheriæ*; Factor 2, a factor appearing to be concerned in the amount of growth of *L. casei*; Factor 3, which seems to be necessary mainly for the production of acid.

Factor 1 occurs in casein hydrolysate, and, using a casein digest medium, *C. diphtheriæ* can be grown without the addition of liver concentrates or any external additions of unknown growth-factors. It has been shown that using an amino-acid medium, this factor is necessary for the growth of *L. casei* in the presence of Factors 2 and 3. Active liver fractions, adsorbed on fuller's earth, have been found inactive for its nutrition until Factor 1 was added, and the activity of fractions extracted by aqueous butyl alcohol is also very much improved by the addition of this factor. Among its distinguishing chemical properties are the following: it is not precipitated by saturation with ammonium sulphate; not extracted from aqueous solution by butyl and amyl alcohols; not extractable by phenol and *p*-cresol; gives no insoluble derivatives with lead, silver, or phosphotungstic acid; gives no insoluble picrate; is not adsorbed on fuller's earth at *p*H 3; is adsorbed on norite at *p*H 3 and eluted by alcohol ammonia.

Factor 2 appears to be responsible for the speed of the initial growth of *L. casei*. Many observations have led to the conclusion that acid production is not directly proportional to the weight of micro-organism obtained. This factor increases largely the amount of visible growth, especially during the first twenty-four hours of incubation. Pollack and Lindner[4] indicate a similar factor in Wilson's bacteriological peptone, and the same result is given by extracts of crude nucleic acid, commercial trypsin, etc.: the properties so far detected include: some precipitation with ammonium sulphate from crude extracts (no appreciable inactivation with proteolytic enzymes); solubility in aqueous butyl alcohol; partial solubility in aqueous amyl alcohol, especially with reasonably purified fractions; adsorption on norite at *p*H 3; very little adsorption on fuller's earth at acid *p*H.

Factor 3. This apparently occurs as a free growth-factor and also in a combined form. It is this factor which seems to be principally responsible for the acid production of *L. casei* ε in our medium. It probably occurs in liver largely in the combined form. This appears to be inactive, but on mild hydrolysis yields the free growth-factor. Factor 3 is more readily separated than the other two. It is not precipitated by ammonium sulphate; soluble in aqueous butyl alcohol; insoluble in aqueous amyl alcohol; gives salts with lead and silver; precipitated by phosphotungstic acid; soluble in phenol and *p*-cresol; adsorbed on norite at *p*H 3; adsorbed with difficulty on fuller's earth at *p*H 3.

All extracts of this factor are persistently and noticeably acid. As an example, it may be quoted that the activity extracted from a neutral solution by butyl alcohol is invariably acid in reaction. This phenomenon is so general that it appears probable that this acidity is a characteristic of the growth-factor itself. There is also some evidence that this factor forms a picrate at *p*H 4.

The combined form of Factor 3 has very different

properties. It is soluble in 50 per cent aqueous alcohol, insoluble in 98 per cent alcohol, insoluble in aqueous butyl and amyl alcohols, not adsorbed by fuller's earth, adsorbed by norite, not soluble in phenol, *p*-cresol, etc.; on hydrolysis with dilute mineral acids or by pepsin, further quantities of Factor 3 can be produced.

A clear-cut and absolute division into an active and inactive fraction has never been obtained; 70–80 per cent of the activity is the most that any one process will yield, so that on purification there is always a loss of material, and the complete separation of the three factors is a matter of some difficulty.

Prof. R. J. Williams has very kindly supplied us with samples of his folic acid, and comparative tests have been carried out with this fraction. The results obtained have not been very satisfactory; and even with the addition of Factor 1, only small amounts of growth and acid production have been found to occur with the media used in these laboratories[5].

We hope to publish shortly a fuller account of this work discussing the methods and media employed; and shall then endeavour to show, so far as possible, the connexion between these factors and the many similar factors obtained by other workers interested in the same field of research.

A New Genus of Terrestrial Algæ

IN the damper hothouses of the Cambridge Botanical Gardens, there occurs in some quantity a green alga growing on fragments of oolitic limestone. It constitutes a new genus (Cladophorella) of Cladophoraceæ, and its discovery is of interest from several points of view. Pieces of the same kind of oolitic rock are present in some of the cooler houses, as well as in parts of the rock garden; moreover, a very similar material has been used in the construction of many of the Cambridge colleges. A search has failed to reveal Cladophorella elsewhere than in the hothouses, so that on present evidence it would appear to be an introduced tropical form. The Cladophorales were the only major group of Green Algæ in which so far no truly terrestrial representatives had been found, and the discovery of Cladophorella shows that the capacity for a subaerial existence is general among the groups of Chlorophyceæ.

The alga consists of a complex system of horizontal threads, readily breaking away from one another at the septa and attached to the rock by elongate, for the most part unicellular, rhizoids. From the horizontal threads arise erect-growing branching filaments reaching a height of 3–5 mm. and forming dense tufts. Growth of the threads is apical. The cell-structure is that of a Cladophora, the vegetative cells possessing a parietal reticulate chloroplast with numerous pyrenoids and a limited number of nuclei internal to the chloroplast. As the erect threads elongate, the bulk of the cell-contents concentrates in the cells at the tips of their branches. These cells develop into akinetes with a thick lamellate membrane and a dense chloroplast harbouring numerous large pyrenoids; there is probably also some multiplication of nuclei. Apart from fragmentation of the threads *in situ*, the akinetes seem to constitute the only means of reproduction. They are readily detached and are no doubt wind-dispersed.

A feature of particular interest lies in the special properties of the surface-layer of the membrane, covering the akinetes and other of the upper cells. This layer, which forms a continuous covering, approximates in many respects to a true cuticle, such as has, so far as I am aware, not yet been demonstrated in an alga. It resists 60 hours immersion in concentrated sulphuric acid and prolonged treatment with a 50 per cent solution of chromic acid. The persisting cuticle, after removal of the acid, stains distinctly with Sudan III or Sharlach *R*, although the stain is in general not very deep. Treatment of fresh material with either of these reagents affords some evidence of staining of the surface layer of the membrane in all parts of the plant, and it seems likely that it may exhibit some cuticularization throughout, though this is only pronounced on the upper parts of the erect threads. Mature akinetes exhibit practically no contraction when allowed to dry in the air of the laboratory and, while other factors may come into play as well, this is no doubt largely due to the properties of the enveloping cuticle.

Carbon Dioxide Content of Atmospheric Air

As a sideline to an investigation on the water vapour content of the upper air, the carbon dioxide content has been determined in a number of air samples obtained by balloon soundings from heights of 4–10 km.

The samples were analysed by freezing out the carbon dioxide and water with liquid air and, after pumping off all the other gases, the pressure of the combined water vapour and carbon dioxide was measured in a McLeod gauge both at 100° C. (p_{100}) and at 0° C. (p_0). By deducting the saturation pressure of water (4·56 mm. mercury) from the latter value, the carbon dioxide pressure was obtained. As the quantity of condensed water was only a few micrograms, the solubility of carbon dioxide in the condensate was completely negligible.

The method of collecting the air samples was developed in collaboration with Mr. L. H. G. Dines, of Kew Observatory, and was similar to that used in obtaining air samples for the determination of the helium content in the stratosphere[1]. The vessel was opened—as described by Dines[2]—by breaking a capillary attached to the sampling vessel, and it was closed by fusing the same capillary by means of an electrically-heated spiral of platinum wire. Even with such a clean method, the danger of contamination by carbon dioxide from the burning of traces of

organic matter on or near the heated parts proved extremely great. The first results gave figures for the carbon dioxide content of the free air which were just as erratic and high as those found by Lepape and Colange[3] in their analyses of upper air samples (0·03–0·13 per cent) from heights of 9–16 km.

In the end, however, a satisfactory technique was evolved, so that, even without air ventilation, samples of air free from carbon dioxide taken under identical conditions in the laboratory gave a contamination of less than 0·001 per cent carbon dioxide. With this improved method and a maximum of air ventilation at the moment of sampling, the following carbon dioxide contents (volume per cent) were obtained from a sequence of twelve air samples taken at 4–10 km. height over England.

0 025	0 025
0 024	0 030
0·028	0·025
0·024	0 024
0·024	0 024
0·025	0 026

With the exception of two samples, which may well have suffered from accidental contamination, these figures show a remarkable constancy.

Analyses of air samples taken on the ground at Kew Observatory, and analysed by the same method, gave values of 0·031–0·035 per cent. Air from the tower of Imperial College, London, gave 0·035–0·037 per cent, while inside the laboratory, according to the state of ventilation, values between 0·041 and 0·107 per cent were found. Analyses by J. S. Haldane and R. H. Makgill[4] showed large variations of the carbon dioxide content (0·021–0·044) even in country air at levels more than 4 ft. from the ground, and still greater amounts on and below the ground. T. M. Carpenter[5], on the other hand, finds in a series of 790 analyses at Baltimore, U.S.A., that variations are limited to a range of 0·028–0·033 per cent.

Thus, while the carbon dioxide content near the ground can be affected by the combustion of fuel and by the respiratory action of living organisms, it appears to be constant in the upper air. From the figures obtained there follows a probable value of 0·025 ± 0·001 per cent. This figure is somewhat smaller than the carbon dioxide content of the sample obtained in the stratosphere over the American continent during the flight of *Explorer II*: this was found to be 0·029 ± 0·002 per cent[6] and seems to be the only reliable figure published so far of the carbon dioxide content in the upper air. But in view of the different analytical procedure and the lack of common standards, it would be premature to speculate whether this difference is due to the geographical position of Great Britain.

My thanks are due to the Director of the Meteorological Office, Air Ministry, for the collaboration afforded and for permission to publish these results, to Mr. L. H. G. Dines, who obtained the air samples by balloon sounding, and to Prof. F. A. Paneth, in whose laboratory this work has been carried out, for his constant interest.

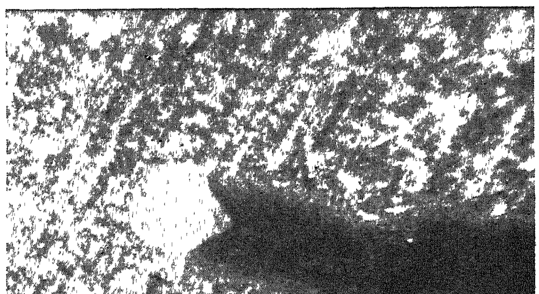
Filiform Underfilm Corrosion of Lacquered Steel Surfaces

IN the course of some work on the corrosion of steel plate surfaces coated with transparent oil-modified synthetic lacquers in atmospheres containing acetic acid and water vapour, the production and growth of the hair-like corrosion tracks known as 'underfilm corrosion' were observed under the microscope. It has been suggested that these corrosion tracks follow cracks in the oxide film separating the metal and the lacquer. The samples were prepared by cutting grids of one inch mesh through the lacquer coating with a razor blade. These were then exposed in a desiccator with a dish containing 5 per cent acetic acid for 24 hours, after which the acid solution was replaced by water.

It was found that the area of exposed metal was quickly covered with a layer of red oxide, and that, at a number of points along the edges of the cuts, radial corrosion started, producing areas under the film which were semicircular in shape and of slowly increasing radius. In some cases when two of these semicircular areas intersected, forming a cusp, a new type of 'filiform' corrosion was set up, which penetrated under the film at a relatively high speed (of the order of one inch per month under the conditions of the test). The tracks varied in thickness between 0·1 and 0·5 mm., but each was practically constant throughout its length. On highly polished sheets the direction of the tracks appeared to be random, although on unpolished mill sheets there was a preference for the direction of the grain of the steel.



The most interesting feature of this phenomenon is the structure of the growing head of the tracks, which is shown in the accompanying photograph with a magnification of 75. The sides of the cusp, of which the angle varies above and below 90°, are extremely sharp and suggest the existence of a membrane, possibly ferric hydroxide. This sharp boundary separates the rusty red track from a blue-coloured area bounded on its forward edge by a semicircular boundary. This appears in the photograph as a light-coloured space. The appearance suggests a bubble of liquid containing ferrous ions, the shape of the forward edge of the bubble being determined by the adhesion between the lacquer and the steel surface, and producing an effect similar to that of surface tension.

It would appear that this particular configuration constitutes a stable regime, which tends to extend the corrosion in the forward direction of the axis of symmetry of the cusp, but shows no tendency to extend in a direction at right angles. In this connexion it has been noticed that if the head of a track approaches an existing track, it is sharply deflected from its original direction, which indicates that the area on each side of an established track is unfavourable to this type of corrosion propagation.

Tracks have been observed with a length several hundred times their own width and still growing with no apparent decrease of vigour. This seems to suggest that the corrosive agent, in this case acetic acid, has been propelled forward undiminished in amount within the bubble as if by a sort of pumping action due to the advance of the V-shaped membrane. This suggestion is supported to some extent by the observation that if a razor cut is made in the lacquer across the path of a growing track, the filiform corrosion regime breaks down as soon as contact is made with the discontinuity in the lacquer.

This phenomenon is probably of very considerable importance in the corrosion of all painted steel surfaces, since it is capable of spreading fairly rapidly from the point of original damage of the film, although in highly pigmented paints the form of corrosion here described could not be observed visually.

Physique and Perseveration

FOUR tests of perseveration[1], the 'S', 'Triangles', 'Mirror Image' and 'Alphabet-Number' tests, were given to 92 boys at the Polish Boys' College, Glasgow. The boys were also classified, according to Kretschmer's well-known types of physique, into four groups, the asthenic, athletic, pyknic and indefinite. The results of the four perseveration tests were pooled, and the whole group was divided into two parts on a scale of 100 equal steps between the lowest and the highest perseverators in the group. The following table was made.

Perseveration	Physique				Totals
	Asthenic	Athletic	Pyknic	Indefinite	
Low	99	23	47	9	178
High	69	21	89	11	190
Totals	168	44	136	20	368

If there were no influence linked with physique which affected perseveration, then the totals in the bottom row should by chance be divided between high and low perseverators in the proportions shown by the right-hand marginal totals. χ-squared calculated on this assumption is 21·15, and, with three degrees of freedom, the probability of such a distribution being obtained by chance alone is less than 0·01. From this it may be concluded that asthenic boys tend to be low and pyknic boys high perseverators, while athletics and boys of indefinite physique are as often high as low. It may be possible to discuss this unexpected conclusion more fully in another publication.

If the four perseveration tests are taken separately, the 'Mirror Image' and 'Alphabet-Number' Tests conform to the general result. The 'Triangles' test suggests that both asthenics and pyknics are high perseverators, and the 'S' test suggests that both are low. Athletics and boys of indefinite physique are indifferent in all four tests.

Homo sapiens in Australia contemporary with *Homo neanderthalensis* in Europe

THE interesting article by Prof. Wood Jones[1] on the recently discovered Keilor skull and its bearing on the antiquity of man in Australia invites attention to the fact that *Homo sapiens* occurs in Australia in a Pleistocene deposit. I should like to stress an important implication of this discovery, namely, that if the age of the skull as suggested by Mahony[2] can be confirmed, a form of *Homo sapiens* existed in Australia when *Homo neanderthalensis* lived in Europe.

Mahony states that the skull was found 18 ft. deep in a river terrace which, at its end near the sea, has a surface height of 60 ft. above low-water mark, and he correlates this with the 40–50 ft. level of Tasmania, regarded by Edwards[3] as Last Interglacial. The altimetric agreement with the Main Monastirian (18·5 metre) sea-level of Europe and other parts of the world is even better, being exact within 2 ft. There is no question that the main Monastirian sea-level dates from the first half of the Last Interglacial, say, about 150,000 years ago. But since the evidence for the age of the Keilor skull is purely altimetric, it is highly desirable that some supplementary evidence be brought forward.

Now, in Europe, the Last Interglacial has furnished remains of *H. neanderthalensis* only[4], and there is ample evidence that *H. sapiens* replaced *H. neanderthalensis* during the first interstadial of the Last Glaciation, and in some areas later, by immigration. This has been recognized widely; it means that *H. sapiens* evolved outside Europe, either during the Last Interglacial or even earlier. This view has found support in the discovery of the *sapiens*-like Swanscombe skull fragment of Penultimate Interglacial age (about 250,000 years ago), and in the *sapiens*-like features observed in Neanderthaloids from Steinheim and Mount Carmel.

The discovery of the Keilor skull makes this suggested greater age of *H. sapiens* appear in a more definite light: if *H. sapiens* had reached south-east Australia by the middle of the Last Interglacial, he must have evolved, presumably in Asia, considerably prior to this date, that is, either very early in the Last, or more likely in the Penultimate Interglacial. The implications of the conclusion are far-reaching. We must expect to find further evidence for *H.* cf. *sapiens* in deposits of the Penultimate Interglacial. Australian man might be the comparatively pure descendant of the primordial stock of *H. sapiens*. His migration to Australia possibly took place as early as during the Penultimate Glaciation, while the sea-level was at its lowest[5]. The Upper Palæolithic culture, which is usually associated with *H. sapiens*, is perhaps much older in Asia than it has been found to be in Europe.

It is to be hoped that the Keilor discovery will

encourage further search for early man in Australia, and also in Asia, in the anticipation that other geologically datable remains and industries be discovered.

Road Accidents and Research

THE persistence of road accidents is evidence of a sociological disorder. They are the painful symptoms, not the malady. An organized attempt to diagnose the disease has yet to be made. Even the symptoms (namely, the accidents) have hitherto been neither recorded nor analysed scientifically. Hence references to statistical records, though sometimes suggestive, are never convincing. The records hitherto have suffered from the directive given to them by a tendentious supposition—that accidents must be due to avoidable carelessness or malignancy. This was officially imputed to some drivers (road hogs); later to all drivers (lust of speed); later still to lack of care in *all* road users without exception (pedestrians, cyclists and drivers), that is, the whole community. Before blaming the 'human factor', inquiry should have been made as to whether the conditions in which road users have to move are such that no large group of human beings could, by taking any reasonable care, negotiate all the emergencies that present themselves.

At present, motor users negotiate them to the point that the average driver carries on through each thirteen years without being involved in more than one minor (injury) accident. It can indeed be shown that by no degree of care can any one driver, cyclist or walker avoid most of the collisions that befall him. This is quite simply because, on the road (unlike the sea or the air), most moving units are not called on or enabled to indicate their intended movement or change of movement.

Mr. M. W. Davies[1] remarks on the lack of correlation between the number of accidents and the number of vehicles in 1931–34. He mistakenly ascribes this "to the increase of accidents in Great Britain in the 'bad' years 1931–34". In fact, these were four 'good' years, but they were made to look 'bad' by an arbitrary change in the method of making the accident records introduced at that date. Every injury 'accident', however trivial, was ordered to be reported by the driver involved under severe penalties, whereas before that date only those were counted that were sufficiently serious to come to the notice of the police. In consequence, the numbers recorded went up with a bound while the fatal accidents, which were not susceptible of this magnification by order, decreased for the first time in history and very notably—from 6,222 to 5,628—in 1931; they remained reduced throughout these four 'good' years, although the number of vehicles increased by nearly 200,000, namely, from 2,237,474 to 2,416,908.

The proportionality of vehicles to accidents is not very relevant as soon as we trouble to probe into such other accident causes as the varying number of traffic units including pedestrians brought on to the roads by more hours of sunshine. Two drought years increased fatal accidents by many hundreds, albeit the general accident trend remained downwards for the four years in question.

The number of 'injured and killed' should not be counted as giving the number of accidents; in a study of accident causation, the accident ratio (that is, number of vehicle accidents per quantity of traffic flow) is all-important.

Among the most important safeguards for the utility of a committee for research into safe traffic flow are: (*a*) it shall not be a committee for research into accidents; (*b*) it shall not be representative of the Ministries interested, or of any road business, but solely of scientific and technical knowledge and skill; (*c*) the remuneration of its members shall not be via these Ministries. These were the safeguards wisely introduced by Lord Haldane when he formed the Aeronautic Advisory Committee of scientific men.

Application of the Principle of Maximum Effect

A REMARK by Mr. M. B. Donald on p. 298 of NATURE of March 11 could usefully be extended. The validity of the application of minimization and maximization to determine optima is not confined to chemistry or to branches of descriptive science and technology. Politicians balance intangible advantages qualitatively; but if the state of a material can be expressed in terms of numbers, a quantitative balance can usually be made by equating *dis*advantages. This can often be done arithmetically.

However, the null principle upon which real and philosophical balances depend sometimes requires more than arithmetic to obtain a scientific statement of a problem. If an empirical attempt is made to solve a problem that involves the null principle, it is merely a matter of chance whether the right solution is reached; hence the empirical approach leads usually to a loss of efficiency and not infrequently to an unintended result. Prof. R. A. Fisher has pointed out to me that that case of the null principle which I have called the principle of maximum effect can, in relation to the black-out, and in terms of lives only, be stated thus: The loss of life is least when the number of lives lost due to accidents and the like arising from any small reduction in lighting is equal to the number of lives gained due to the reduced assistance given to enemy action by the lighting visible to the enemy. Any departure from this results in avoidable loss of life.

The question of method in relation to effectiveness of invention has been discussed by Mr. C. Turnbull in articles in Vol. 15 (1942) of *Distribution of Electricity*. This series merits a wider publicity than can be given by a house organ. Many community relationships being based upon number and statistical distribution, or being otherwise amenable to scientific treatment, I suggest that there is sufficient material for an attack upon the general question of the application of scientific principle in its widest sense to problems of living.

INDUSTRIAL RESEARCH IN INDIA

MR. J. J. GHANDY'S presidential address to the Section of Engineering and Metallurgy at the thirty-first Indian Science Congress, held at Delhi, on "Industrial Research, with Special Reference to India", reviews the development of industrial research in India and the work of the Board of Scientific and Industrial Research.

Mr. Ghandy said that the Control and Research Laboratories of the Tata Iron and Steel Company at Jamshedpur, completed in 1937, are specially mentioned as among the finest laboratories attached to any single steel-producing unit in the world; yet industrial research in India is still sporadic and unsystematized, although its importance as the chief instrument of progress increases. A review of the position and organization of research in Germany, Great Britain, the United States and the U.S.S.R. leads to the conclusion that the Government, universities and industry in India must be assigned distinct research functions although working in close collaboration. The Council of Scientific and Industrial Research should correspond to the Committee of the Privy Council for Scientific and Industrial Research in Great Britain, and consist of prominent industrialists, economists and scientific men with the main function of laying down broad principles of policy, co-ordinating activities and receiving financial grants from the Government.

The Board of Scientific and Industrial Research should concern itself largely with science, while the industrial application of scientific research would be the concern of the Industrial Research Utilization Committee. In Mr. Ghandy's view, the broad functions of the Board would be to plan national, scientific and industrial research in collaboration with the Industrial Research Utilisation Committee under the general direction of the parent Council; to develop facilities for executing the national research programme, by setting up laboratories for chemical, metallurgical, physical, fuel and food research, etc., stimulating the growth of private research institutes and laboratories and encouraging the American fellowship plan for this purpose; and to apportion research schemes to its own and private and university laboratories. It should also control, supervise and co-ordinate scientific research activities and technical education, thus ensuring proper collaboration between Government, industry and science; as well as distribute grants to research institutes and individual workers when necessary. It should formulate and submit its general recommendations annually to the parent Council for approval.

As at present, the Board should operate through a number of research committees, each committee being responsible for research in a particular branch of science, with a director of that branch as secretary. The Industrial Research Utilization Committee should be an industrial committee with much wider functions, co-operating with the Board on one hand in formulating a national research programme, for which it would provide the industrial basis, and on the other operating through a chain of industrial committees covering the different groups of industries. This Committee should also devise methods for the utilization of researches completed by the Board, and formulate rules regarding the taking out of patents and the collection and distribution of royalties. The Board of Scientific and Industrial Research should make its own laboratory facilities available to duly qualified workers, and allow industries to conduct research on specific problems with their own research workers in these laboratories on the lines of the American research associate plan.

Mr. Ghandy also suggested a supreme academy of sciences representative of private research associations and academies and eminent scientific men from the universities to collaborate with the Board in the general planning and direction of scientific research. The Board should provide the universities with financial assistance both for the extension of staff and laboratory facilities and for scholarships for post-graduate research, while the universities should give facilities for industrial fellowships for the investigation of specific industrial problems. The Government scientific services require strengthening, and while they should be given the fullest possible measure of autonomy, they should co-operate with the Department of Scientific and Industrial Research in the enunciation of policy. A scientific news agency and greater attention to publicity and the dissemination of scientific knowledge are also advocated.

TRUTH IN ANTHROPOLOGY

MR. VERRIER ELWIN has made notable contributions to anthropology in India. In his remarkable monograph on the Baiga, he has shown that he can get deeper into the life of a primitive tribe than any of his predecessors in that field, while his second monograph, on the Agaria, has shown that he is as well able to present the life of a primitive craftsman and iron-smelter as that of the primitive hunter, agriculturist and poet which makes a Baiga. It must be confessed, however, that his presidential address to the Section of Anthropology and Archæology at the Indian Science Congress at Delhi last January is far from being the happiest of his efforts. He calls it "Truth in Anthropology"; but the matter that follows the title puts one in mind at once of jesting Pilate, for it fairly bristles with controversial opinions stated dogmatically as truths. Worse than that, to allege, for example, that Frazer, Westermarck and Briffault have been influenced in any way by the political bias of their sources of information is a very improper and unjust imputation on the scientific integrity of three great men, of whom two at any rate are no longer alive to defend their reputations. To suggest of Briffault, of all people, that his "only standard of judgment appears to be political respectability", shows an ignorance of his work so profound as to make Mr. Elwin's strictures as worthless as they are deplorable. Let him take and read "Reasons for Anger" before he talks further of Briffault and political respectability. To decry the value of Frazer's work is, of course, rather the fashion, and those who do so rarely seem to have read what he wrote or to realize that, had he not written, it is doubtful whether they would ever have written either. Mr. Elwin adds nothing to his stature by swelling their numbers.

It is difficult after this to attach a great deal of importance to Mr. Elwin's attack on the Indian Census for classifying the primitive tribes of that peninsula as other than Hindu. It may be indeed, as he says, that Hinduism is an animistic religion, but even if all Hindus be animists, that does not make all animists Hindus. It is true that Hinduism is a receptive creed; that many of the most orthodox Hindus hold that all other creeds are mere back-

slidings from their truths. At the same time, he would be a bold man who would therefore label Christians, fireworshippers, Manichæans or Mormons, let alone Muslims, as Hindus. It may well be admitted that it would have saved a great deal of trouble to Census authorities if aboriginal tribes had all been included as Hindus; it must indeed be admitted that a nice discrimination of the point at which they become Hindu is difficult in many tribes which have sophisticated sections of their population entirely Hinduized while other sections remain primitive in belief and practice.

Yet the distinction which Mr. Elwin would apparently like to make between aboriginals and non-aboriginals is no easier to draw on racial or on cultural lines, and in the pursuit of truth in any event difficulty of attainment is neither here nor there. Mr. Elwin himself might just as fairly be suspected of a political or communal motive in advocating the return of aboriginal tribes as Hindus, as the Census officers are so suspected by him for trying to distinguish them from Hindus. It may be admitted that an entirely satisfactory criterion of Hinduism has not yet been found, but persons who do not observe caste, who disregard the religious authority of Brahmans, who do not hold the doctrine of *karma* can with difficulty be regarded as Hindus at all. One writer at the recent census of India—Mr. Webb, Census superintendent of Rajputana and author of "These Ten Years"—goes so far as to make untouchability actually the test of Hinduism in the case of tribes doubtfully within its pale. The Chamar, he says, is untouchable because he deals in cowhide and the flaying of cows, in pursuits, that is, defiling to a Hindu; the Bhil follows practices just as repugnant to a good Hindu, but he is not untouchable; this can only be because it is recognized that since he is not a Hindu, those practices do not put him beyond the pale of decent society. The contention has some force, even though many Bhils are undoubtedly Hindus.

The amazing statement, again, that the creation of Excluded and Partially Excluded Areas "was largely the work of a distinguished anthropologist at the Round Table Conference", even if it contains any portion of the truth, which may well be doubted, is very far indeed from being the whole truth. The areas referred to were administered under special regulations long before the Round Table Conference was even conceived of, and their so-called "creation" was a natural and, as administration officers saw it, an almost inevitable development in the process of applying the reforms to Indian political life. Anyone interested in pursuing the point might refer to Chapter 7 of Part ii of Vol. 1 of the Indian Statutory Commission's Report of 1930, and to Chapter 2 of Part iii in Vol. 2.

There are other very questionable statements of a similar kind. In one case a writer is quoted as expressing an opinion, and then taken to task for giving information. But what he gave was a statement not of fact but of an opinion derived, perhaps quite legitimately, from such information as he did succeed in obtaining. The adjective "Tylorian" is used as a derogatory epithet—and so forth. All of which is a great pity, for Mr. Elwin has something to say, and we agree with him entirely in his statement that "truth in anthropology demands a scrupulous adherence to the highest rules and standards in field-work". No doubt presidential addresses are not fieldwork, but that is no ground for any relaxation in them of the high rules and standards of a scientific approach, nor for the imputing of disingenuous motives to workers whose outlook and views prove unpalatable to the temporary occupant of the chair.

J. H. HUTTON.

PARASITIC DISEASES OF MAN IN RELATION TO THE WAR

FIVE addresses given to a conference on parasitic diseases held by the New York Academy of Sciences in March 1943 have been published (*Ann. New York Acad. Sci.*, 44, Art. 3, 189–262; 1943). In his introductory address, Prof. H. W. Stunkard points out that the study of animal parasites is no longer an academic one, because the diseases they cause constitute one of the most pressing problems of to-day and to-morrow. The gravity of the problem is increased by the dispersal of American (and, we would add, other) troops to all parts of the world, where they are acquiring parasitic diseases. These troops may, both now and after the War, bring back to their home countries parasites not normally prevalent there. Not all these parasites will be able to spread in these home countries, either because the local climatic and other conditions are not favourable to them or because the intermediate hosts necessary for the completion of their life-histories do not exist. But it is known that some parasites have been able to acquire new intermediate and definitive hosts in countries to which they have been transported. Prof. Stunkard gives as an example of this the sheep liver fluke, and he considers the possibility that the human schistosomes may, for example, acquire the ability to develop in some snail in America. The risk of the introduction of new parasites into the home countries is real enough to require energetic action. We in Great Britain, with much colonial and tropical experience to guide us, have been always aware of it; and it is evident that the United States' authorities have also taken the problem in hand.

Already during this War parasites have done appreciable harm to both Allied and Axis troops. Trichiniasis has put out of action at least one battalion of German troops in Norway (*Bull. War Med.*, 3, 236; 1942), and German commando and other troops have suffered from this disease on their Eastern front. We know also something of the precautions taken by the Germans to protect their Afrika Korps from disease in Egypt and the tropics. Their problems would seem to be now solved for them by the removal by the Allies of all possibility of the entry of Axis troops into the tropics.

For the Allies, however, these problems increase as their victories extend. Prof. Stunkard states that it has been reported that the United States' defeat at Bataan was due as much to the malarial parasite as to other causes. He estimates that a million or more United States troops may acquire parasites and that their fighting efficiency may be proportionately reduced. Dr. Coggeshall, dealing with current and post-war problems associated with human Protozoan diseases, says that United States troops are already acquiring Protozoan infections from native reservoirs at an alarming rate. Amœbic dysentery and malaria are the chief dangers in this field, although other parasites (for example, the trypanosomes) must not be forgotten. Malaria, which is one of the major enemies of both sides in war, can persist in man for

years, especially if it is quartan malaria. Dr. Coggeshall cites the case of a Greek who acquired quartan malaria in Greece and, after thirty-seven years in Denver, gave his blood for blood transfusion and communicated quartan malaria to the recipient of it. Dr. Matheson, at the same meeting, recorded the transmission of the parasite of malignant tertian malaria (*Plasmodium falciparum*) to a six-year-old child in Ithaca, N.Y., through receiving a blood transfusion from her father, who had never shown symptoms of the infection. E. L. Lozner and L. R. Newhouser (*Amer. J. Med. Sci.*, **206**, 141–146; 1943; and *Bull. War Med.*, **4**, 353; 1944) conclude that there is no likelihood of the transmission of malaria by blood *plasma* used for transfusions. They did, however, transmit malaria to two out of 35 recipients of plasma taken from patients infected with either quartan or malignant tertian malaria, but the plasma given to these two cases had been preserved for only one day in the liquid state. Malaria was not transmitted when the plasma of malarial patients was preserved in the liquid state at room temperature for two weeks, or when it was either frozen and then stored at − 20° C. or dried from the frozen state.

The control of the vectors of malaria is another important problem. *Anopheles quadrimaculatus*, which can transmit all three human species of the malarial parasite, is the chief vector of malaria in the United States and is abundant as far north as the Canadian border. The corresponding malarial problem in Great Britain has been considered by Sir A. McNalty (NATURE, April 17, 1943, p. 440), and the British species of mosquitoes and their control are dealt with by Lieut.-Colonel Sinton and P. G. Shute (*Min. of Health Mem. Med.*, 238; 1943). J. F. Marshall (NATURE, **149**, 568; 1942) and Dr. A. B. Williamson and J. F. Marshall (*Brit. Med. J.*, Sept. 11, 1943, p. 332) have studied the breeding of mosquitoes in war-time static-water tanks in Britain. The damage that malaria can do to armies in the field is indicated by the figures given by Dr. T. T. Mackie in his address in the American symposium on the clinical features of parasitic diseases. To give only one example of these, Mackie says that the French force of 120,000 men in Macedonia in 1916 was reduced by malaria to an effective field force of only 30,000, that the British Macedonian force had 30,000 malaria cases in 1916 and 70,000 in 1917, and that the Germans had similar losses; so that Plasmodium alone immobilized these armies.

Problems of control among large numbers of people are difficult enough in times of peace. These difficulties are increased in war-time, and added difficulty is introduced by rapid transport. The aeroplane itself may introduce infected hosts and vectors of all kinds of diseases (Jackson, W. P., *Virginia Med. Monthly*, **69**, 29; 1942; and *Bull. War Med.*, **3**, 629; 1943). Coggeshall points out that practically all the foreign air traffic to the United States, except that to and from Great Britain, originates in the tropics, where airports are usually in places in which sanitary measures are inadequate or absent; these airports are also surrounded by native villages the inhabitants of which are used as labourers and who are infected. The risks involved are exemplified by the accidental introduction in 1930 of *Anopheles gambiæ* into South America; this was followed by an epidemic of malaria which caused 100,000 cases and a minimum of 14,000 deaths. The insect was eradicated by the joint efforts of the Brazilian Government and the Rockefeller Foundation (Soper, F. L., and Wilson, D. B., *J. Nat. Malaria Soc.*, **1**, 5; 1942 and *The Lancet*, Jan. 22, 1944, p. 120). Failure to perform this difficult feat might have resulted in disaster to all the tropical areas of the western hemisphere.

Coggeshall's further remarks on the virulent malaria and dysentery seen by him among Poles coming out of Russia to Persia in 1942, and the risk of their spreading these diseases to India, East Africa and other places to which they were dispersed, make clear the risk inherent in mass migrations of peoples, especially if, as is scarcely avoidable in war-time, they are in poor health and encounter strains of a parasite to which they are not accustomed. Such strains produced, after the War of 1914–18, secondary epidemics of malaria in England, Germany (6,000 cases) and Russia (3 million cases west of the Urals, half the population of Georgia and the deaths of two-thirds of the population in villages near Tiflis). These figures recall the ravages of typhus and plague, and remind us that the vectors of disease caused by bacteria and viruses may also be carried by aeroplane. This aspect of the problem was dealt with in an address by Dr. R. Matheson on "Arthropods as Vectors of Human Diseases". So far as malaria is concerned, we should do well, says the *Lancet* (March 18, 1944, p. 380), to be warned by the experience of France, where malaria, introduced in 1939 by infected Spanish refugees, has persisted since that date in the Canet and Saint-Cyprien regions of the Pyrénées-orientales.

That the French National Committee of Liberation is already tackling the problems of the parasites, as well as those of other diseases, in the French African Colonies, is indicated by a special medical section of the Brazzaville Conference (*The Lancet*, April 1, 1944, p. 440). The proposals made include the creation of large mobile units to seek out and treat illness and deal with problems of sanitation, and the establishment of a central institute of hygiene and research and, after the War, a medical school and an international bureau of public health.

Dr. N. R. Stoll, taking as the title of his address "Changed Viewpoints in Helminthic Disease: World War I vs. World War II", gives a summary of modern views on the control of hookworms, Trichinella, tapeworms, the flukes of the Orient and other helminth parasites. He outlines our changed views on the epidemiology of diseases caused by this kind of parasite and on human resistance and immunity to them. Stoll quotes Leiper's list of facts (*Brit. Med. J.*, July 19, 1924, p. 110) about the helminth which the public health worker should remember. Helminths do not multiply within the human body; their eggs or embryos have to leave the human body and are not infective to man when they leave him, but have to undergo first a development outside man, either in the outside world or in an intermediate host; the environment necessary for this development varies with different species; the helminth enters man by the mouth or by penetration of the skin and many species then have to make extensive journeys inside the human body; few helminths are specific to man and their spread can be prevented by breaking the life-cycle. The knowledge gained about helminth parasites during recent years should, says Leiper, enable us eventually to eradicate helminth infestations of man, if it is properly used. A big "if", some would say; but the task is possible. Under the conditions which we may expect after the War, it will indeed be formidable.

G. LAPAGE.

HIGH-VOLTAGE CIRCUIT-BREAKER TECHNIQUE

Two important papers were read in London before the Institution of Electrical Engineers on March 30, one on restriking voltage as a factor in the performance, rating and selection of circuit-breakers, by Messrs. J. A. Harle and R. W. Wild, and the other on the influence of resistance switching on the design of high-voltage air-blast circuit-breakers, by Messrs. H. E. Cox and T. W. Wilcox.

In the first of these, Messrs. Harle and Wild point out that the behaviour of circuit-breakers when breaking short-circuit currents depends on a number of factors which include circuit power-factor, recovery voltage, earthing conditions, and current asymmetry. A further condition of severity is the restriking-voltage transient and its attribute, the rate of rise of restriking voltage. The paper shows the effect of this severity factor on the performance of plain-break oil circuit-breakers, oil circuit-breakers fitted with arc-control devices, and air-blast circuit-breakers. Compared with the relatively small effect that rate of rise has on plain-break and arc-control oil breakers, its importance for the performance of air-blast breakers is emphasized, and recommendations are made for its utilization in the rating, testing and selection of these breakers.

The conclusions reached may be summarized as follows. Plain-break oil circuit-breakers and oil circuit-breakers with arc-control contacts are relatively unaffected by the rate of rise of restriking voltage and hence the specification of its value is not essential, provided the circuit-breakers are tested in accordance with British Standard 116 under the severity conditions of the Association of Switchgear Testing Authorities. In air-blast circuit-breakers it is essential to take account of the rate of rise of restriking voltage when rating, testing and selecting, and in consequence they must be rated in terms of megavolt-amperes at a rated voltage and at a rate of rise of restriking voltage. Methods are proposed for specifying minimum rates of rise of restriking voltage for each megavolt-ampere rating and voltage, the adoption of which enables an economic range of switchgear to be designed which will meet all average conditions of severity in service and permit economic selection of circuit-breakers to be made.

A simple method of checking the suitability of any breaker rated as above for normal conditions of service is given, together with data for checking the suitability of any breaker for more unusual conditions of service. The method involves calculating the fault megavolt-amperes in the usual manner and checking that the proportion of the fault megavolt-amperes contributed locally by generators, transformers, and the like, is not in excess of an amount appropriate to the breaker rating. Circuit-breakers rated in the manner advocated can also be selected for more severe conditions by adopting the methods described for reducing circuit severity in service. Proposals are made for testing air-blast circuit-breakers, including synthetic tests for certain types of high-voltage circuit-breakers the megavolt-ampere ratings of which are in excess of testing station outputs.

In the second paper, Messrs. Cox and Wilcox review the various problems which are met in designing high-voltage circuit-breakers, and the way in which the application of resistance switching confers another degree of freedom upon the designer in meeting the many conflicting requirements. It is first shown that a circuit-breaker must not only break its rated breaking current, but must also limit the value of surge voltage which it causes while it is opening the circuit. This can be brought about by limiting the electric strength of the breaker contact gaps.

An experimental method of determining the electric strength of the nozzles under air-flow conditions is explained, followed by a discussion of the means by which resistance switching enables the designer to control both the nozzles independently. A 132-kV. breaker designed in conformity with the conclusions reached is described and test results are given for a full-scale test equipment. The paper then gives an analysis of the validity of 'unit testing' as applied to multi-break breakers with resistance switching, as compared with the use of the present two-part testing applied to oil circuit-breakers in accordance with British Standard 116, part 2. Finally, proposals are made for a series of type-test duties to be applied to air-blast circuit-breakers, in order to prove compliance with their breaking-capacity ratings.

The conclusions reached by Messrs. Cox and Wilcox are as follows. An air-blast circuit-breaker, like an oil circuit-breaker, causes over-voltages when it breaks a circuit under certain conditions. The prospective value of the over-voltage depends upon the circuit constants and upon the rate at which the arc is de-ionized. Under conditions very often realized in practice, the prospective value of such over-voltage can be dangerously high, and the actual value reached is limited only by restriking of the breaker gap. The latter thus not only has to be proportioned to break its rated breaking current, but also to limit, by restriking, the values reached by switching over-voltages. The breaker capacity and electric strength of a nozzle are interdependent, unless the restriking-voltage transient can also be controlled. The latter can be modified by means of resistance switching, so that by its introduction the breaking capacity and electric strength of the breaker can be controlled individually and independently.

By combining resistance switching with series multi-breaks, the distribution and exact shape of the restriking transient across each break can be controlled accurately. Thus 'unit testing' of such breakers is completely valid. This will greatly increase the scope of existing test plants for testing high-breaking-capacity breakers. The breaking-capacity type tests given in British Standard 116 for oil circuit-breakers are not entirely satisfactory for air-blast breakers. Among several minor changes it is necessary to add a test duty to prove that the breaker adequately limits switching over-voltages. The switching over-voltage which is most convenient to produce on test plants is that due to current-chopping in an inductive circuit. The voltage-limiting effect of the breaker can be demonstrated by taking a series of breaking tests at a current at which multiple current-chopping occurs. A duty comprising only three tests is considered inadequate to demonstrate the capability of the breaker to limit over-voltages, and it is suggested that twenty tests should be included. These should be sufficient to take care both of the variations in arc length at final interruption and also the statistical nature of the breakdown of air-gaps under rapidly applied voltages.

FORTHCOMING EVENTS

Saturday, May 20

NUTRITION SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 10.30 a.m. —Conference on "Budgetary and Dietary Surveys of Families and Individuals", Part 2 (to be opened by Prof. V. H. Mottram, Mrs. Barbara Callow, Dr. C. P. Stewart and Miss M. C. Broatch).

BRITISH INSTITUTE OF RADIOLOGY (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 2.30 p.m.—Annual General Meeting; at 3.15 p.m.—Prof S. Russ: "The Man Silvanus Thompson" (Twenty-third Silvanus Thompson Memorial Lecture).

INSTITUTE OF PHYSICS (joint meeting of the INDUSTRIAL RADIOLOGY GROUP and the MANCHESTER AND DISTRICT BRANCH) (in the Physics Department, The University, Manchester) at 2.30 p.m.—Mr C. T. Snushall: "Filters and Intensifying Screens—their Applications in Light-Alloy Radiography".

Monday, May 22

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. R. W. Moore: "Visual Education".

Tuesday, May 23

SOCIETY OF CHEMICAL INDUSTRY (joint meeting of the CHEMICAL ENGINEERING GROUP and the INSTITUTION OF CHEMICAL ENGINEERS) (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. J. E. Hurst: "Improvements in Acid Resisting Silicon Iron Alloys".

EUGENICS SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr Margaret Hadley Jackson: "A Medical Service for the Treatment of Involuntary Sterility".

Wednesday, May 24

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—The Rt. Hon. the Earl De La Warr, P.C.: "Flax Production in War, and its Prospects in Peace".

PHYSICAL SOCIETY (in the Physics Department of the Imperial College, Imperial Institute Road, South Kensington, London, S.W.7), at 5 p.m.—Dr. W. S. Stiles: "Current Problems in Visual Research."

Thursday, May 25

BRITISH INSTITUTION OF RADIO ENGINEERS (LONDON SECTION) (at the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6.30 p.m.—Dr. Hilary Moss: "The Electron Gun of the Cathode Ray Tube", Part 1: "Limitations in its Performance".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

DRAINAGE AND IRRIGATION ENGINEER by the Gambia Government —The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E. 950 A) (May 24).

LECTURER IN ELECTRICAL ENGINEERING, and a LECTURER IN MECHANICAL ENGINEERING with special reference to Workshop Technology or Heat Engines—The Principal and Clerk to the Governing Body, Wigan and District Mining and Technical College, Wigan (May 25).

LECTURER in charge of the DEPARTMENT OF BOTANY—The Registrar, University College, Leicester (May 27).

LECTURER IN ELEMENTARY SCIENCE AND PHYSIOLOGY at the Chelsea College of Physical Education (temporarily evacuated to Borth, near Aberystwyth)—The Principal, Chelsea Polytechnic, Manresa Road, London, S.W.3 (May 27).

LECTURER IN ENGINEERING SCIENCE at the County Technical College, Wednesbury—The Director of Education, County Education Offices, Stafford (May 29).

TECHNICAL ASSISTANT IN AGRICULTURAL ECONOMICS—The Acting Registrar, The University, Leeds 2 (May 30)

ASSISTANT MASTER or MISTRESS to teach MATHEMATICS, with some SCIENCE, in the Junior Technical School of Engineering of the Willesden Technical College, and possibly some MATHEMATICS in Part-time Day Courses—Dr. E. Davies, Education Office, Vernon House, 163 Willesden Lane, London, N.W.6 (May 31).

SCIENCE TEACHER, with primary qualifications in Physics or in Chemistry, a TEACHER OF MATHEMATICS, and a LECTURER in ENGINEERING SUBJECTS, at the County Technical College, Stafford—The Director of Education, County Education Offices, Stafford (May 31).

DIRECTOR OF THE INSTITUTE OF MEDICAL AND VETERINARY SCIENCE, Adelaide—The Agent-General and Trade Commissioner for South Australia, South Australia House, Marble Arch, London, W.1 (May 31).

DEPUTY ENGINEER of the Sheffield Waterworks Undertaking—The General Manager and Engineer, Waterworks Office, Town Hall, Sheffield 1 (May 31).

CHAIRS OF PHILOSOPHY, ZOOLOGY and COMPARATIVE ANATOMY—The Registrar, University College, Cathays Park, Cardiff (May 31).

ENGINEER AND SURVEYOR to the Esher Urban District Council—The Clerk to the Council, Council Offices, Esher, Surrey (endorsed 'Engineer and Surveyor') (May 31).

DEPUTY CHIEF ENGINEER (location, City of Manchester)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. D.834XA) (May 31).

LECTURER IN THE MECHANICAL ENGINEERING DEPARTMENT—The Director, Robert Gordon's Technical College, Aberdeen (May 31).

ASSISTANT LECTURER AND DEMONSTRATOR (woman) IN CHEMISTRY —The Principal, Royal Holloway College, Englefield Green, Surrey (May 31).

BACTERIOLOGIST on the staff of the Water Pollution Research Laboratory of the Department of Scientific and Industrial Research—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.2248A) (May 31).

CHAIR OF BOTANY—The Registrar, The University, Sheffield (June 1).

LECTURER IN BIOLOGY to take Nature Study with Froebel students, Biology with advanced class, and to train post-Graduate Biology students—The Principal, Maria Grey Training College, at the Training College, Castle View, Dudley, Worcs. (June 1).

LECTURER FOR PRACTICAL MATHEMATICS and MECHANICS, LECTURERS (2) for MECHANICAL ENGINEERING, and a LECTURER for ELECTRICAL ENGINEERING, in the Department of Engineering—The Principal, West Ham Municipal College, Romford Road, Stratford, London, E.15 (June 5)

DEMONSTRATOR (man or woman) IN THE PHYSIOLOGY DEPARTMENT —The Warden and Secretary, London (Royal Free Hospital) School of Medicine for Women, 8 Hunter Street, Brunswick Square, London, W.C.1 (June 9)

ENGINEER AND MANAGER of the Manchester Waterworks Department —The Secretary, Waterworks Department, Town Hall, Manchester 2 (June 10).

INSPECTORS (temporary) by the Board of Education (1) MECHANICAL OR ELECTRICAL ENGINEERING (Reference No C 2125A), (2) AERONAUTICAL ENGINEERING (Reference No C.2124A)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting the appropriate Reference No.) (June 10).

LECTURERS to take the following subjects for Evening Classes up to Matriculation standard: ELEMENTARY MATHEMATICS, GEOGRAPHY, CHEMISTRY, PHYSICS, BIOLOGY, LOGIC—The Director of Education, The Polytechnic Regent Street, London, W.1 (June 12).

CHAIR OF NATURAL PHILOSOPHY, United College, St. Andrews—The Secretary, The University, St. Andrews (June 15).

ASSISTANT HYDROGRAPHIC SURVEYORS by the Kenya Government Public Works Department—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No.E.904A) (June 17).

ENTOMOLOGISTS in the Medical Departments of Uganda, Northern Rhodesia, and the Tanganyika Territory, for general entomological work; with special emphasis on the investigation of tsetse fly and mosquito problems in the field as well as in the laboratory—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F 2421A) (June 17)

LECTURER IN ENGINEERING in West Africa—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.836A) (June 21).

ENGINEERING DRAUGHTSMAN for the Department of the Comptroller of Development and Welfare, West Indies—The Secretary, Overseas Manpower Committee, Ministry of Labour and National Service, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. 1373).

WORKSHOP STEWARD (temporary) for the maintenance of the ENGINEERING AND BUILDING WORKSHOPS—The Principal, Municipal College, Southend-on-Sea.

TECHNICIAN mainly for research work, experience in histological technique essential—The Registrar, King's College, Newcastle-upon-Tyne.

HEAD LABORATORY STEWARD (man or woman) in the DEPARTMENT OF PHYSICS AND TELECOMMUNICATIONS—The Secretary, Woolwich Polytechnic, Woolwich, London, S.E.18.

HYDROGRAPHICAL SURVEYORS for the Basrah Port Directorate, Iraq—The Ministry of Labour and National Service, Appointments Department, Sardinia Street, Kingsway, London, W.C.2 (quoting Reference No. O.4962S).

ADMINISTRATIVE ASSISTANT (male) in connexion with the scheme of the Ministry of Agriculture and Fisheries for the provision of technical advice to farmers—The Dean of the Faculty of Agriculture and Horticulture, The University, Reading.

TEACHER (man or woman) of CHEMISTRY and BIOLOGY—The Principal, Technical Institute, Longport Street, Canterbury.

TEACHERS (2, full-time) of ENGINEERING SUBJECTS to help with the development of Higher National Certificate courses—The Principal, Technical Institute, Gravesend.

MASTER for ENGINEERING SUBJECTS (MECHANICAL), including Engineering Drawing, and a MASTER for MATHEMATICS and MECHANICS—The Principal, Erith Technical College, Belvedere, Kent.

LECTURER IN BACTERIOLOGY to students preparing for the National Diploma in Dairying—The Principal, Studley Agricultural College for Women, Studley, Warwickshire.

RECRUITMENT AND TRAINING OF TEACHERS

YOUTH LEADERS AND TEACHERS IN YOUNG PEOPLE'S COLLEGES

IN the second part of the McNair Report* it is significant that the sections on the supply, recruitment and training of youth leaders and teachers for young people's colleges have been grouped together. This implies a clear recognition that if the young people's colleges are to be successful, the more formal methods of the preceding school period will have to be dropped, and some of the spirit of informality which accompanied the growth of the youth movement and which has kept it vigorous and attractive will have to be preserved. Further, since the two services deal with approximately the same groups of young people, one attempting to meet their needs on the basis of compulsory and the other on the basis of voluntary attendance, Sir Arnold McNair's Committee insists that the foundations of the youth service must be laid during the years immediately following the break with full-time attendance at school.

Any attempt to draw up detailed proposals for the young people's colleges, which are not yet in existence, would have been a misuse of the Committee's time and energy, and it has therefore confined itself to a statement of broad principles.

Although the youth service differs in that it has a history, it presents a peculiar problem because, while that history has been in the main a story of voluntary initiative, to-day it is being woven into the pattern of education for which public authorities are responsible. This involves co-operation between voluntary and statutory bodies of a kind which calls for adjustment and tolerance rather than rigid rules and, if organization merely becomes an end in itself, its existence as part of the national system of education will be extremely precarious.

Many youth workers are anxious about what they call the 'professionalization' of work among young people and believe that it may result in a loss of spontaneity and freedom which is characteristic of the best voluntary work. The Committee strongly emphasizes that these fears about 'professionalization' will only be falsified if the quality of men and women recruited to the service of youth is sufficiently high to maintain the best of its traditions, and if statutory and voluntary bodies co-operate to put the needs of young people first and to leave administration and standardization to find their proper, but subsidiary, place.

Work with young people is so varied that those engaged in it can be classified in many ways. Two broad divisions are recommended in the report. First, full-time workers such as organizers, wardens and heads of large centres or institutions, who are almost invariably paid workers, and secondly, part-

* Teachers and Youth Leaders. Report of the Committee appointed by the President of the Board of Education to consider the Supply, Recruitment and Training of Teachers and Youth Leaders. (London : H.M. Stationery Office.) 2*s*.

time workers who may be paid or unpaid. In outlining a scheme for the training of youth leaders it must be recognized that this will in no way reduce the need for a tremendous number of voluntary workers to whom the service of youth owes its inception and high traditions.

The Committee points out that there is no recognized qualification for a youth leader, and there are few courses of systematic training. In the past these have been provided by the voluntary organizations and vary in duration from a few months to two and a half years. As a result of all these courses not more than 150 trained workers have been produced. Since the outbreak of war, the Board of Education has taken a hand in the sphere of training. Some of its staff have themselves conducted a number of short courses lasting from one to two weeks, and also in 1942, the Board announced its willingness to grant financial assistance on a student capitation basis to institutions and organizations which were prepared to conduct approved courses. These courses were to be regarded as experimental and were not to lead to a recognition of any course as providing a full qualification for youth service work (Circular 1598).

These different types of courses, for which more than three hundred students have enrolled, are serving a three-fold purpose. A number of war-time youth workers are being given a better background of knowledge and experience ; a variety of organizations are experimenting in the new field of training, and, equally important, the Board of Education, local education authorities, the universities, training colleges and voluntary organizations are being brought together in the work of training. The experiences gained from these courses will be invaluable in the framing of future ones leading to the attainment of nationally recognized qualifications.

Another anomaly in the service of youth which the Committee underlines is the lack of a national scale of salary. Current educational journals include advertisements ranging from £100 (with board) to £250 for youth leaders and wardens and £200–£400 per annum for organizers. There is great disparity in the salaries offered for comparable posts, and provision for pensions for youth service workers as such do not exist. Even the maximum salaries offered at present are not sufficiently high to attract the best type of personnel for this all-important work.

The age of entry to work in the youth service varies between wide limits. Since the service of youth caters for young people ranging from fourteen to twenty years of age, it is essential that there be corresponding maturity on the part of those who may be called upon to guide and advise them. It is important, too, that the wide field from which youth leaders and organizers are at present drawn should not be restricted. Among part-time and voluntary workers there are few professions which are not somewhere represented. Whatever system of training is devised for youth leaders, this invigorating variety must be preserved.

With these general considerations as a working basis, the Committee then discusses and makes various recommendations on the future supply and training of youth leaders.

On the assumption that one leader will be required for about every three hundred boys and girls between fifteen and eighteen years of age, it is estimated that 5,000–6,000 full-time youth leaders will be required. Since physical activities constitute a very important part of the interests of youth, and since many other activities which young people pursue with zest make great physical demands on those older people who help to plan them, it is reasonable to assume that the active working life of the youth leader will be less than that of the teacher. Adding to this the normal depletion through death, illness or premature withdrawal to other types of work, it is anticipated that, once the full establishment is in being, an annual recruitment of about three hundred youth leaders will be required. The Committee rightly indicates that "this flow of 300 a year will not be achieved without the establishment of a profession involving approved courses of training of a satisfactory standard which lead to a recognised qualification and of a service in which adequate salaries are paid and acceptable conditions of service are secured".

Training is regarded as essential, although it may not be practicable to make it compulsory in the immediate future. The youth leader works with human material, and the unguided experience through which he now has to learn his profession is only too often bought at the expense of those whom he seeks to help. Moreover, complete absorption in work with young people to the exclusion of a personal life of his own is one of the temptations that beset a leader, and his education should give him something which minimizes the danger of his becoming unduly preoccupied with youth. The leader, like the teacher, should be a well-balanced, fully developed individual.

At the time of his first appointment to a post, it is suggested that the youth leader should have achieved a fairly high standard in some field of knowledge or in some craft of his own choosing. He should have a good working knowledge of the elements of citizenship. He should possess considerable understanding of the psychology of young people and their individual, social and industrial background, as well as a genuine interest in one or more of the many activities in which young people freely engage, such as music, drama, crafts of all kinds, gymnastics, games, and so on. It is essential, too, that he should have some experience of actual work with young people, including what is involved in the organization and business management of groups, clubs or institutions. Most important of all, he must be the kind of man whose personality is acceptable to young people and who has a genuine sense of vocation for his work.

For the beginner it is recommended that the training course should extend over at least three years. At least a quarter, and in some cases a half, of the course should be practical work, and should not mean merely a series of brief visits of observation to a number of institutions concerned with young people. It should include substantial periods of continuous

work in one or more institutions or among one or more groups of young people in different geographical and industrial areas. In order to minimize a possible lack of coherence in such training, a full-time tutor should be responsible for planning the study and practice of a defined and small group of students. Ideally, each course, because of its practical nature and the co-operation with active youth workers, should itself be a contribution to the youth work of the locality, and the training system as a whole should influence the work throughout the country.

The institutions offering courses of training should keep continuously before them the need for devising the proper machinery of selection. A new entrant to the training courses might either be tried out in some youth service work before he makes a firm application for training, or might be given a preliminary interview sufficiently in advance of the beginning of the course to enable him to do some practical work prior to a final decision being reached about his suitability for training. The first term or two of the training course should be regarded as probationary. An important and long-sighted recommendation is that a student's achievements during training and his fitness for full-time professional work should not be decided by the results of an examination at the end of the course. The core of the assessment must be the capacity to live and work with young people. As a great deal of experimental work is already in progress, the Committee strongly recommends that the Board of Education should obtain an intimate knowledge of the conduct and results of the present emergency courses which are being aided under Circular 1598. Much guidance for the future might be obtained if the experience of those conducting these courses was pooled, analysed, and made generally available. A mass survey of the type of training essential, with the help of existing organizations already in touch with the country's youth, for example, the Central Council for Health Education and youth organizations, might well be initiated now.

The minimum age at which a man or woman should in normal circumstances take up full-time work must be carefully considered. Maturity is the essence of the problem when dealing with boys or girls or young men and women of 15–20 years of age who have reached, or are on the way to, economic and social independence. The psychological and social problems with which a leader has to deal differ profoundly from those which face a teacher in a primary school or even a secondary school. As a general rule, therefore, local education authorities and voluntary organizations should not appoint young men and women to full-time posts before the age of twenty-three.

Shorter courses of training are recommended for potential youth leaders who have already achieved knowledge and experience which is relevant to their personal life or to their professional competence as youth leaders. These will include university graduates, holders of social science diplomas, men and women who have had considerable practical experience as part-time youth leaders and wish to qualify for full-time work, and business or professional men and women who may be unfamiliar with the structure of society as it affects young people or who need some stimulus to the revival of his or her cultural interests. Save in exceptional circumstances, no course of training should be less than one year.

For some years after training, the youth leader—or teacher—would be expected to serve in the capacity for which he has been specifically trained. If, after some years of experience, a youth leader—or teacher—seeks to transfer to another part of the educational field, and is suitable, he should be enabled to do so. Since the course of training which is proposed for youth leaders is comparable in content, standards and length with that proposed for teachers, it is necessary that the salaries of youth leaders should be comparable with those of teachers, and that service as a youth leader should be pensionable. Transfer from one service to the other should be facilitated by the necessary linking of superannuation arrangements and the provision of suitable short courses of training.

During their training, youth leaders should not be segregated. If properly representative of the interests of youth, the area training authority, which the Committee recommends as the organization responsible for the training of teachers, is also the right body to plan and provide courses of training for youth leaders. The universities, technical colleges, schools of art and training colleges are all accustomed to the maintenance of standards in their own field, and they must see that in academic subjects, in social studies, in crafts and skills, the standards of youth service training are built up and maintained at a high level. The Committee further recommends that each area training authority should be adequately representative of youth organizations and should appoint a person qualified to direct such training for leaders in the youth service as the area is called upon to provide. The first five years of the training should be regarded as an experimental period and, for the time being, the Board of Education should recognize the appointment to full-time posts of those who have not been trained, but are deemed otherwise to be suitably equipped.

To return to the training of teachers for young people's colleges. If these colleges are not to be subordinated to the fluctuating needs of industry and commerce and to the frequently narrow requirements of the 'jobs' which young people are doing, the periods when the young people attend them must be regarded primarily as educational periods during which young people are also at work, finding their feet in industry, commerce, agriculture or domestic activities. Only if these periods are regarded as educational will the colleges develop into institutions calculated to inspire loyalty and affection from young people generally.

With this consideration in mind the Committee discusses the problem of the staffing of young people's colleges. It is estimated that the colleges will require the services of about twenty thousand teachers, involving, on the basis of one day's attendance a week,

a replenishment of about a thousand a year. How should they be recruited and how trained?

Young people's colleges, some of which may be residential, will be self-contained institutions, each with its own staff. They will be full-time institutions with, for the most part, full-time staff, but providing for students who will attend only part-time, and that under compulsion. This situation will present many difficult problems of organization and will complicate the planning of courses of study and activity. The uniform characteristic of the students will be that they are at work earning their living, or, if not at work, living at home and elsewhere in a state of semi-independence compared with the restrictions imposed when they were in full-time attendance at school. This change of status must be taken into account in the staffing of young people's colleges, but, on the other hand, its significance should not be exaggerated.

For young people's colleges, particularly, specific arrangements should be made for entry to the teaching profession of those who have had experience in some other profession or occupation. A rich field of recruitment will be the Service men and women, who have been labouring under great difficulties and yet built up a scheme of adult education the elasticity and breadth of which Great Britain has not seen before. These men and women will be eminently suitable for young people's colleges. Local education authorities should see that their experience is used to the full.

But while the staffs of young people's colleges will need to be persons with a wider experience of the world than is usual among the main body of teachers, the colleges will also require teachers with good qualifications in English, history, science, music, art, physical training, etc., as well as highly qualified teachers of technological and commercial subjects. It would be unwise to regard the colleges as institutions in which there is no place for the teacher with normal secondary or other school experience, or as institutions which require a kind of music or physical education wholly different in character from that to be found in other types of school or college. The staffing needs of young people's colleges can be met only by mobility of staff throughout the whole educational system.

While the need for mobility among teachers is essential, it is also vitally important that a common field for their education and training be ensured in order to avoid the segregation of particular groups of persons in training. The area training service would again be the appropriate body to undertake the training of teachers for young people's colleges, for thus would mobility be made more practicable.

In examining the supply and training of youth leaders and of the service of teachers in young people's colleges, the McNair Committee has entered practically unexplored fields. The service of youth is a recent development, and, save for a few pioneering experiments, young people's colleges do not at present exist. Nevertheless, the extent of its recommendations leaves little doubt that, within its terms of reference, the Committee has done its work admirably.

RESEARCH ON THE PHOTOGRAPHIC PROCESS

The Theory of the Photographic Process
By Dr. C. E. Kenneth Mees. Pp. xi+1124. (New York: The Macmillan Company, 1942.) 60*s*. net.

DR. C. E. K. MEES, with the help of the Kodak Research Laboratories, has written a book that will be for many years the standard authority on the photographic process. His title describes the book as an account of the theory; but theory is not conceived in a narrow sense as the counterpart of experiment, but rather as including almost everything about photography except its practice. The first chapters deal with the emulsions, what they are made of and how they are prepared; the action of light is then described, the processes that take place in photographic materials under its influence and the large number of theories which has been advanced to account for them. Development and fixation are then discussed, again with the emphasis on the details of changes that take place in emulsions and on attempts to explain them in terms of physics and chemistry. There are further chapters on sensitometry, on the nature of the developed image and on the photographic aspects of sound recording. Finally an account is given of the use of dyestuffs for the production of colour-sensitive film, and for desensitization.

It is remarkable how the advance of physical science often leads to an understanding of the new and unfamiliar long before it can explain phenomena apparently more commonplace. For example, Clerk Maxwell's mathematical genius enabled him to predict the properties of electric waves before they were shown to exist, and as a result the theory and the practice of wireless transmission have advanced side by side, neither proceeding far in advance of the other. The progress of the science of electronics has been similar; there was no great technical advance in the use of cathode rays before their nature was understood, nor in the use of photo-electricity before Einstein's law and the quantum theory gave it a theoretical background. In fact, in the wide field of electrical engineering, the very existence of which could not have been anticipated until the end of the eighteenth century, theory has at times been in advance of practice and seldom far behind it. On the other hand, some of the properties of inorganic matter which have been familiar to mankind for a very long time still somehow resist the attempts of theoretical physics to explain them. Outstanding is the problem of the nature of the liquid phase, and the fact that most solids melt; while solids and gases present no particular mystery and allow their equations of state to be calculated from first principles, this is not true of liquids. More important are perhaps the problems relating to strength of materials, in particular of metals. The enormous body of knowledge on their mechanical properties and on how their hardness and ductility can be influenced has been gained without the help of any theory to show what arrangements of atoms in the materials are responsible for these properties. So great is our ignorance on the theoretical side that it is still possible for experts to argue as to whether an ideally perfect crystal would be very hard or very soft.

Photography, or rather the art of making and processing emulsions, has, in the last ten or twenty years, been emerging from the state in which the

science of mechanical strength is now and gaining a status similar to that of electronics. Dr. C. E. K. Mees' book, therefore, is very welcome at the present time, both as tracing the development of the subject in the days when there was no guiding theory and not much connexion between photographic theory and the rest of physics, and the present position when this is no longer true. The advance in the last few years has been that we now feel that it is 'only to be expected', taking into account what is known from other sources about the behaviour of halide salts, that an emulsion of silver bromide would be light-sensitive and retain a latent image which could be made visible by a reducing agent such as a developer.

The picture given in Dr. Mees' book of the formation of the latent image is now quite definite. Silver halides, in common with many other salts, decompose under the action of light, and metallic silver is formed as little lumps on the surface of the halide grain. After prolonged exposure these can be seen under the microscope, and can be shown by the methods of X-ray spectroscopy to have the same structure as silver in bulk; and much evidence is given to show that the latent image after normal exposure, though too small to be seen, is of the same nature; the number of atoms in each speck may be some tens or hundreds. Particularly interesting is the account given of the researches of Dr. S. E. Sheppard, who showed that in a sensitive emulsion the halide grains must have on the surface a number of specks of silver sulphide. These he called sensitivity specks, and their role is to concentrate the silver atoms formed by the action of the light. They are formed by the presence in suitable gelatines of organic sulphur compounds, due to the predilection of cattle for sulphur-bearing plants, such as mustard—a most fortunate accident. Rabbits do not share this taste, and gelatine from their tissues is inactive, so that, if it is used for the preparation of emulsions, a low sensitivity results.

As regards the mechanism by which light releases silver atoms from the halide crystals, and the way in which these atoms are concentrated in the sensitivity specks, the theory put forward by Dr. Gurney and the present reviewer is in the main accepted and some account is given of the experimental work based upon it which has been carried out by the Kodak Research Laboratories both in Great Britain and the United States. According to this theory, the action of the light is to make the halide grains photoconducting, as a result of which the sensitivity specks acquire a negative charge; they then build up a speck of metal by electrolytic conduction within the halide grain, the positively charged silver ions moving through it towards the negative charge. Particularly interesting experimental work has followed the suggestion that development takes place by the same process, the developer charging the silver specks negatively, and the silver moving towards the latent image through the body of the grain, so that the developed silver is pushed out of the grain in long threads. The electron microscope has enabled very beautiful pictures of the developed image to be taken which suggest that it must be formed in this way; the developed silver grain is not solid, but consists of a tangle of metallic threads between 100 and 1000 A. in diameter, which are held in the space occupied by the original grain simply by the action of the surrounding gelatine. Excellent examples of these photographs, with a magnification of 40,000–50,000, are shown on p. 312 of the book under review.

Interesting and gratifying though it is to see photography gaining the status of an exact science with a theory behind it, it is impossible not to be impressed with the achievements made before this was so, and also perhaps with the number of apparently fortuitous circumstances which have made this advance possible. It is now known that a very large number of metallic salts can be reduced photolytically in suitable circumstances; for example, alkali halides, if illuminated with a wave-length that they absorb and held at a temperature, about 400° C., at which they show ionic conductivity. However, to be useful photographically a metallic salt must absorb light in the visible part of the spectrum, must show ionic conductivity at room temperature, and must on reduction give a metallic residue that does not react with water or oxidize in air. It is fortunate that silver halides and a few other salts have all these properties. That a substance with the properties of gelatine exists seems even more fortunate; it has to be rigid enough when wet to hold the halide grain in position against the somewhat large disruptive forces that must occur during development, and yet be porous enough to allow the large molecules of the developer to pass freely through it. Moreover, it was extremely helpful, for the early production of sensitive emulsions, that it contained organic sulphur compounds capable of attacking the halide grains and forming the sensitivity specks.

It would be wrong to suggest that the science of photographic emulsions does not still contain many interesting problems awaiting solution; perhaps the action of sensitizing dyes is the most outstanding. Dr. Mees' work will be of service in bringing these problems to the notice of physicists and chemists outside the photographic industry, and showing them that the study of emulsions can be interesting and important as much for the information that it gives about the interaction between matter and light as for the influence that it has on the technical applications.

The present reviewer has taken a reviewer's freedom to deal in detail only with those parts of the book which interest him personally; an organic chemist or a sound engineer would naturally have chosen quite different parts, and any review of so comprehensive a work is bound to be somewhat one-sided. In fact, photography now covers a very wide field of science, and this is well brought out in the book.

N. F. MOTT.

MATHEMATICAL PHYSICS

Methoden der mathematischen Physik

Von Prof. R. Courant und Prof. D. Hilbert. (Published and distributed in the Public Interest with the consent of the Alien Property Custodian under License No. A. 82.) Band 1. Zweite verbesserte Auflage. Pp. xv+469. 8 dollars. Band 2. Pp. xiv+549. 8 dollars. (New York: Interscience Publishers, Inc.; London: H. K. Lewis and Co., Ltd., 1931–1937.) 2 vols., 14 dollars.

THESE two volumes are photo-lithoprints of the second edition of Vol. 1, issued in 1930, and Vol. 2, issued in 1937. The first volume contains seven chapters as follows: 1, the algebra of linear transformations and quadratic forms; 2, the development of an arbitrary function in series; 3, the theory of linear integral equations; 4, the basic principles of the calculus of variations; 5, the oscillation and eigenvalue problems of mathematical

physics; 6, application of the calculus of variations to eigenvalue problems; 7, special functions defined by eigenvalue problems.

The original design of writing this work arose from the observation that while mathematics had in the past received inspiration from the close relation which exists between analysis and the intuitive conceptions of physics, the source of this inspiration was tending to run dry. Analysis was becoming more and more an end in itself and the physicist tended more and more to estrange himself from an understanding of the problems and methods of the analyst. No doubt there were faults on both sides; indeed, it is largely true that mathematics tends to outstrip its applications and it is probably too much to ask the physicist to interest himself in those parts of a subject for which he can see no immediate applications. Nevertheless, one cannot remain blind to the fact that this forging ahead on the part of mathematics has served the physicist well, for example, in the development in the present century of the theory of relativity and of quantum theory.

However that may be, Courant saw in this growing estrangement a danger signal to both sciences, and he set about writing a book which should effect a reconciliation by helping the student and preparing the ground for the research worker. This is from every point of view a worthy aim and one which has been ably fulfilled by the presentation in one place of a clear and scholarly account of mathematical methods which appeal to the physicist for their applicability and to the mathematician for their rigour. Moreover, the bringing together of a well-chosen selection from original papers and other published work makes smooth the path of the student to an extent which anyone can appreciate who has had to delve for himself. The usefulness of the work is further enhanced by the attempt to make each chapter substantially independent, thus affording the opportunity of selecting just that topic on which the reader requires orientation.

The second volume is largely independent of the first in that it aims at a systematic treatment of partial differential equations in their relation to mathematical physics. This volume contains seven chapters as follows: 1, preliminary notions; 2, general theory of partial differential equations of the first order; 3, linear differential equations of higher order; 4, differential equations of elliptic type and potential theory; 5, differentials equations of hyperbolic type in two independent variables; 6, differential equations of hyperbolic type in more than two independent variables; 7, solution of boundary and eigenvalue problems by the calculus of variations.

In the first volume many particular problems are considered in which linear partial differentials of higher order are concerned. In the second volume a systematization is attempted with the object of making the subject more approachable.

In mathematical physics it is seldom that the totality of all solutions of a differential equation is required; even the finding of a special class of solutions is not the object. Rather the aim is usually to pick out one particular solution which is to satisfy relations laid down by the problem itself, initial conditions or boundary conditions. In this respect it is important to observe that boundary value problems and partial differential equations of elliptic type belong naturally together, while initial value problems belong to equations of hyperbolic type such as arise in connexion with oscillations and radiation.

From the point of view of mathematics a physical problem is only properly stated when the solution (1) exists, (2) is unique, and (3) depends continuously on the data, the condition of physical determinateness. Throughout this volume the above general considerations are kept clearly before the reader, the emphasis throughout being on the broad connexion of ideas. The last chapter is very interesting, for here the direct method of the modern calculus of variations is applied to establish the existence and uniqueness of the solution of equations of elliptic type. The principle here is to replace the boundary problem by a variation problem in which a function is sought which has the necessary properties of differentiability, and which renders the appropriate variation expression a minimum. It is not assumed that such a minimum exists, but a lower bound d certainly does. There then exists a sequence of functions which are admissible in the variation problem and for which the variation expression tends to d. This sequence of functions, called a minimal sequence, does not necessarily converge, nor, if it does, is the existence of the derivatives of the limit function evident. But it can be shown that it is possible from the minimal sequence to extract a subsequence defining a function which has the required properties of differentiability and which satisfies the differential equation.

L. M. MILNE-THOMSON.

METALLURGY IN EVERYDAY TERMS

Metals in the Service of Man

By Arthur Street and William Alexander. (Pelican Books, A.125.) Pp. 192+20 plates. (Harmondsworth and New York: Penguin Books, Ltd., 1944.) 9*d*. net.

THE purpose of this admirable little work is abundantly fulfilled—that of bringing home to the general reader the importance which metallurgy now occupies in our industrial life. While serving this useful purpose it will, nevertheless, be read with delight by those who already have a wider knowledge of the subject. Although not putting forward a text-book, the authors have succeeded in overcoming the difficulties which are inherent in summarizing so broad a field and this in a manner and with an accuracy of statement to which academical exponents of the subject could take very little exception.

The great merit of the authors of this book is the simplicity of language used in an exposition of matters relating, more particularly, to the character, structure and behaviour in use, of metals and alloys. It has the quality and value of the spoken word rather than the more formal phraseology of the text-book. For this very reason it should be of particular interest to those who are faced with the introduction of this subject to students, and it is to be hoped that the authors may find time and opportunity to demonstrate still further their gifts of exposition for the benefit of those who need some guidance in framing elementary courses of instruction in these important matters. The authors must have derived considerable enjoyment from the compilation of this short account of 'metallurgy without tears', and in making apt use of homely similes with which to press home fundamental principles. Their friendly artist must have shared this enjoyment in devising his quaint and original illustrations, which are diverting and yet convincing.

S. W. SMITH.

Wave Filters

By Dr. L. C. Jackson. (Methuen's Monographs on Physical Subjects.) Pp. vii+107. (London: Methuen and Co., Ltd., 1944.) 4*s.* 6*d.* net.

THE wave filter is the fundamental necessity of all telecommunication work which is not simple telephony. Carrier-telephony and voice-frequency telegraphy, which enable us to pass tens or even hundreds of times the quantity of information the basic systems permit, could not exist without the wave filter. The basic theory dates only from Campbell some thirty years ago. Since then, Zobel, Shea, Starr, Cauer, and many others have derived alternative methods of approach and practical schemes for arriving at economic designs of filters which are to fulfil more exacting conditions of operation.

The incorporation of quartz crystal elements as lowly damped resonant circuits gave a new degree of freedom in design, and permits the union and separation of hundreds of telephonic channels on a single circuit. The attainment of electrical recording for gramophone disks, and the perfection in so far as it was possible in the so-called acoustic reproduction of records, both resulted from applying what had been solved for electrical circuits to mechanisms intended to operate over a wide range of frequency. Acoustic filters for attenuating specific frequency-bands also followed along the same lines.

The difficulty for a student approaching the subject is either the mass of information contained in the standard text-books, or the skeleton data provided in handbooks or in single chapters in texts on wider subjects of electrical communication or radio. The present author tries to meet the student by outlining the above-mentioned subjects, with just as much theory as will give the student confidence in using any of the great mass of formulæ available in the actual production of filters. The author does not treat at any length the usage of filters in practice, for example, the impedance conditions which are imposed when filters are used in parallel, or any special conditions imposed by the association of filters with modulators. In the space available in these excellent monographs, the author has presented the subject in concise and readable terms, and if there is nothing original, the assistance which he affords the student of filters is ample justification.

L. E. C. Hughes.

The Subject Index to Periodicals, 1942

Issued by the Library Association. Pp. x+175. (London: Library Association, 1944.) 77*s.* net.

THE seventeenth volume of "The Subject Index to Periodicals" covers the year 1942 and presents no new features. It is compiled on the plan of the 'dictionary catalogue', articles being entered under specific headings in alphabetical order. The principle is not carried to inconvenient extremes; for example, articles on the individual vitamins are collected under vitamins and are not dispersed under their respective names, while cross-references play an important part in linking up related subjects. Explanatory matter in square brackets is often added where the titles do not sufficiently indicate the subject. The preparation of the "Index", as formerly, has largely depended on the vast resources of the British Museum, while from September 1940 until October 1943 the editor and his staff were accommodated in the National Library of Wales, Aberystwyth. With some important exceptions, including, for example, NATURE, *Engineering*, the *British Medical Journal*, periodicals covered by the *Agricultural Index*, *Engineering Abstracts*, *Index Medicus*, *Journal of the Royal Society of Arts*, *Petroleum Institute Abstracts*, *Photographic Abstracts*, *Science Abstracts*, *Journal of the Textile Institute* and the *Royal Meteorological Society Bibliographies* are not indexed; but scientific workers will find the "Index" a useful means of picking up signed articles on scientific subjects in leading general periodicals, as well as in tracing authoritative articles on a wide range of social and economic problems, education, reconstruction, etc., in the leading reviews and periodicals.

Reports of the Progress of Applied Chemistry

Issued by the Society of Chemical Industry. Vol. 27, 1942. Pp. 546. (London: Society of Chemical Industry, 1943.)

THE progress of applied chemistry, as illustrated by publication during 1942, is summarized by this report, which conforms to the established pattern. The following fields are reviewed: general, plant and machinery; fuel; gas, destructive distillation, tar and tar products; mineral oils; intermediates and colouring matters; fibres, textiles and cellulose; pulp and paper; acids, alkalis, salts, etc.; glass; ceramics, refractories and cements; iron and steel; non-ferrous metals; electrochemical and electrometallurgical industries; fats, fatty oils and detergents; plastics; resins, drying oils, varnishes and paints; rubber; leather; soils and fertilizers; sugars and starches; the fermentation industries; foods; fine chemicals and medicinal substances; photographic materials and processes; sanitation and water purification.

Great activity in the direction of synthetic chemical production by the petroleum industry is noted. Magnesium at 1*s.* per lb. is, if measured by volume, cheaper than aluminium at 7½*d.* per lb., and its use in aircraft construction is substantial. With reference to the potentialities of the electrochemical and electrometallurgical industries, it is estimated that in the British Empire some 107 million horse-power of water-power is available, and that of this only about 6 per cent has yet been developed. Progress in the soilless culture of plants is briefly summarized, and this technique of commercial food production is considered to possess every prospect of success. The blackening of potatoes is attributed to hydrolysis of an iron complex which is said to result from growth in soil deficient in potassium but rich in nitrogen.

Health and Hygiene

A Comprehensive Study of Disease Prevention and Health Promotion. By Lloyd Ackerman. Pp. xii+895. (Lancaster, Pa.: Jaques Cattell Press, 1943.) 5 dollars.

THE scope of this book is very wide. In providing a guide to the layman for the proper regulation of his mental and physical life, the author runs riot from physiology to psychology with nothing missed in between. It is doubtful if anyone could ever plough his way entirely through to the end, although this would certainly be an enlightening task. As a book of reference, a modern 'home doctor', this one has much to recommend it. The advice is always sound and common sense, and the explanations are clear and simple. Teachers, medical men, or lecturers preparing talks on any branch of hygiene for youths or adults would find here much useful and relevant information.

FUNGI AND MODERN AFFAIRS*

By DR. J. RAMSBOTTOM, O.B.E.
British Museum (Natural History)

IT is a little surprising that fungi should have received so little consideration from academic botanists, for they are more numerous in species and in individuals than is the rest of the plant kingdom. They are classed in the vegetable kingdom, for with the old divisions, plants, animals and minerals, there is nowhere else for them. But they are not plants in the ordinary sense of the word as they have no chlorophyll and there is no evidence that they were derived from organisms so provided. A great amount of research has been carried out during the last half-century to ascertain the precise methods by which green plants build up carbohydrates; but comparatively little attention has been paid to the manifold and diverse physiological processes by which fungi obtain their nutriment. In their search for food, fungi play many parts in the drama of Nature and in modern affairs.

To many the word fungus conveys the idea of something mysterious or foreboding: to others mushrooms and toadstools. J. Bauhin appeared to combine the two ideas when he derived the word from *funus* (funeral) and *ago* (to put in motion), a derivation which John Ray considered appropriate even if possibly not correct.

What is a mushroom? The term is often loosely applied to those larger fungi which are edible, it being assumed that only the field mushroom and possibly one or more of its near allies are safe to eat; the rest, assumed to be poisonous, are grouped together as toadstools. But the assumption puts the facts the wrong way round, for there are less than a dozen species which are in any way poisonous; the vast majority are harmless. It would be illogical to speak of even the three hundred or more edible species as mushrooms and the others as toadstools; it seems preferable to call all agarics 'toadstools', restricting 'mushroom' for the species of the genus Psalliota: in this way, moreover, some of our insular and peculiar prejudice against them might be toned down.

Toadstools have been eaten from the earliest times. There is no reference to them in the Bible, but classical writers leave us in no doubt that fungi were well known as peculiar organisms of strange growth, so well known indeed that they were the subject of puns. Accidents sometimes occurred and, as these seem to be specially noted, it has been assumed by some that the use of fungi as food was regarded as too dangerous to be indulged in. What is more probable was that fungi were a common food, but accidents were especially noted because of the difficulty of distinguishing between wholesome and poisonous species. It was comparatively simple to get a knowledge of what plants and fruits are safe to eat for they are easy to recognize again, they are lasting, and. even if annual, they are constant in their time and place. Consequently they all had names. Fungi, on the other hand, are difficult to describe, and the fleshy ones are of irregular occurrence and of short duration. For this reason we find rules for distinguishing between edible and poisonous species rather than names and descriptions. Many of these rules are still current—'peeling', and the non-blackening of a silver spoon being the most widely believed, and this throughout Europe, possibly owing to them being repeated in the old herbals. All are utterly worthless, even dangerous. There is only one real test. Many have tried it, and as there are numerous records of experiments which ended in disaster, we have a mass of evidence which relieves us of the necessity of personal trial.

It is only in Great Britain that toadstools are rejected as food. Eighty years ago, five or six species were on sale in Covent Garden Market; but later only the mushroom, wild or cultivated, was displayed. It is hard to account for the British prejudice against them. It has been suggested that it is because of our high standard of living, or alternatively because of the absence of well-wooded country: but these do not explain the fear most people have of them.

In Continental countries with hard and long winters, fungi are dried and pickled and form a staple food while the frosts last; they also serve in place of meat during religious fasts. In all Continental countries fungi are sold in the markets, and many towns have special fungus markets. Usually there is some sort of control, and the number of species allowed to be sold varies from half a dozen to more than three hundred.

Though in Great Britain the chief use of toadstools is as appetizing additions to other dishes, they have a certain food value. There is need of more precise information on this, for many of the old analyses led to extravagant claims. Darwin recorded that the Terra del Fuegians eat no vegetable food except Cyttaria and a few berries, whereas Lettow-Vorbeck recounts that when, during the East African campaign of the War of 1914–18 the difficulties with food had reached a most embarrassing stage, the German troops were able to carry on owing to finding enormous quantities of edible fungi which were to them as manna was to the children of Israel.

There are a number of species which have always had a good reputation as edible, which moreover are easy to identify and which cannot readily be confused with any poisonous forms. For those not making a special study of the subject, it is advisable to learn to recognize some of these, rather than to experiment with others about which all that is known is that they are not among those regarded as poisonous.

The most deadly poisonous species is *Amanita phalloides* (including the two white varieties or closely allied species *A. verna* and *A. virosa*). It is responsible for practically all the recorded deaths from fungus poisoning and the death-rate is more than 50 per cent —indeed, it has been put as high as 90 per cent. There is a characteristic period of quiescence after the fungus is eaten, on an average twelve hours, though it may be as long as forty. Death may occur on the first day, but is usually on the third or fourth day. There are apparently four poisons contained in this species: Amanita hæmolysin (phallin), a glucoside readily destroyed by heat and digestive juices; Amanita toxin with a complicated and indefinite chemical structure; and according to the work of F. Lynen and U. Wieland (1937), phalloidin, which is quickly acting though destroyed by heat, and an additional slower-acting toxin. Death through eating the cooked fungus is apparently due to the heat-resistant Amanita toxin. Cures have been reported by the use of a 'sérum antiphalloidien' prepared at the Pasteur Institute; by intravenous injection with 20 per cent glucose solution; by intravenous injection with 10 per cent sodium chloride solution; by

* Substance of three lectures at the Royal Institution, delivered on February 15, 22 and 29.

administering the finely chopped up stomachs of three rabbits and the brains of seven.

Amanita mappa, formerly considered as very poisonous, is edible but not worth eating. *Amanita muscaria*, which contains muscarin, mycetoatropin and choline, does not cause death in healthy people. The symptoms of poisoning usually simulate alcoholic intoxication, though there are occasionally gastro-intestinal disturbances. *Amanita pantherina* produces similar symptoms.

The remaining species which are in any way dangerous, raw or cooked, are *Lepiota helveola, Entoloma lividum, Inocybe Patouillardi, Boletus Satanas* and *Gyromitra esculenta*, though some other species are very indigestible and consequently may cause disturbance.

Claviceps purpurea (ergot) is a poisonous fungus of another group. The two different types of ergotism, the convulsive and the gangrenous, are now well known. Five alkaloids have been isolated from ergot: ergotinine, ergotoxine, ergotamine, ergotaminine and ergometrine. As its name suggests, ergosterol was first extracted from ergot; histamine also. The use of ergot in childbirth is mentioned by Lonicer in 1582 in the first record of the fungus. At present ergot is the only fungus which figures in the British Pharmacopœia.

Fungi, being without chlorophyll, have a physiology which in many ways is more animal-like than plant-like. Obviously there are two main sources of food, living organisms and dead organic material. Fungi make use of both—they parasitize all kinds of living organisms, and there is no sort of organic matter not liable to attack. But though they are responsible for the greater part of plant diseases and they cause destruction to stored products of every kind, the changes they bring about are not all to our detriment as living organisms. They act as scavengers reducing dead material into substances available for plant life, and moreover prevent the cluttering up of the earth's surface. The action of soil fungi on plant material was overlooked when untreated jute sandbags were filled with sand and even ordinary earth at the outbreak of the present War. The modern compost heap is a contrivance to bring about the breaking down of similar cellulose substances.

Forest trees are subject to attack by larger fungi as well as by microscopic forms. Timber from such trees is unsuitable for most purposes and, moreover, if not properly seasoned, may continue to rot. Fallen logs and stumps have a characteristic flora, and several of the species occur on wooden fences, gate-posts and similar structures; *Lentinus lepideus*, for example, attacks wood pavement blocks, telegraph poles and railway sleepers.

If wood is to be preserved, it must be kept dry or treated with some fungicide. The chief agent of destruction of structural timber is *Merulius lacrymans*, the dry-rot fungus: there are other fungi causing dry rot, but the damage they produce is trivial. If timber is properly seasoned and then kept dry by ventilation so that it never contains as much as 20 per cent moisture, the fungus will not attack it; otherwise damage is almost certain. At the present time, the amount of dry rot in London calls for serious attention. It is easy to understand how houses which have been severely bombed are liable to have their timber affected, but blast has cracked water-pipes with a consequent seepage of water through the walls; leaves and other rubbish have caused overflows which run down the walls; shelters have been constructed so that ventilation and even water-courses have been interfered with; ventilation bricks have been stopped up to prevent entrance of gas; or sand-bags which became rain-sodden propped up against walls, often over air-bricks; houses left unattended, with no heat and leaky roofs; water-tanks and pipes bursting, water-taps left running in requisitioned buildings—all have played their part in bringing about a good deal of unnecessary waste. Furthermore, there is need for some scientific control over new housing plans or we shall have a repetition of the troubles which affected whole building estates after the War of 1914–18.

In addition to causing diseases of trees, microscopic fungi cause disease not only of crops but also of wild plants. The most striking point about the flora of bombed sites is the rapid appearance of special fungus parasites, as for example *Bremia Lactucæ* on groundsel. The idea that disease is a result of civilization is very attractive to some minds—but is entirely false.

Fungi are the main causal agents of disease in plants. The losses in different crops vary normally from 2 to 50 per cent: figures for the U.S.A. for wheat, oats and barley in 1935 due to rust alone were estimated at 277, 185 and 53 million bushels respectively. There are many ways of combating fungus attacks, the most obvious being the use of fungicides. Much depends upon having a thorough knowledge of the life-history of the parasite as well as that of the host plant, for then the fungus can be tackled at its most vulnerable stage.

Some varieties or races of plants are immune to the strain of fungus parasite common in the neighbourhood, and much work has been done in the attempt to breed immune races. But it is frequently overlooked that there is often as much variation in the parasite as in the host. Thus the problem of producing a wheat immune to black stem rust theoretically necessitates the building up of a resistance to 177 physiological races, though, practically, only the local strains present in any one area need be considered.

Less than a century ago, when the parasitic nature of many diseases was beginning to be suspected, fungi were thought to be responsible for many human affections. This was a consequence of Schoenlein's discovery in 1839 of the fungus causing favus, which was immediately followed by Lagenbeck's describing the fungus of thrush, and soon afterwards by Gruby's description of ringworm. With the gradual recognition of the predominance of bacterial diseases and the abundant problems they presented, mycology, except for the obvious dermatophytosis and actinomycosis, has not received the attention due to it, especially in Great Britain. Many of the ring-worm group are able to live parasitically on domestic animals; some are known to live saprophytically on organic debris and others have been reported as capable of infecting living plants. Athletes' toe (Trichophyton spp., Epidermophyton) has become increasingly common in Great Britain during the past few years and is prevalent in certain sections of the Fighting Services. But there are many less obvious diseases which have been studied principally in France and America. That they exist elsewhere is shown by the recent recognition of histoplasmosis (*Histoplasma capsulatum*) in Great Britain. The symptoms of this disease are protean; they may simulate kala azar or pulmonary tuberculosis—and

the prognosis is bad. A recent discovery by C. W. Emmons that small desert rodents constitute an important natural reservoir of *Coccidioides immitis*, the cause of coccidioidal granuloma, is of importance. This disease has been known for about half a century in North and South America and was thought to be soil-borne. The Medical Research Council has recently appointed a committee to report on the situation of medical mycology in Great Britain.

Animals other than those domesticated are also liable to fungal disease. Insects particularly are affected, whole groups of fungi being entomogenous; as, for example, the Laboulbeniales with about 120 genera and 1,500 species, so well monographed by Thaxter. Moreover, it has been shown recently by C. Dreschler that there are a number of species, Entomophthoraceæ and Hyphomycetes, which parasitize nematodes, amœbæ and other small soil inhabitants.

The extent of the damage by fungi to stored products of all kinds is only gradually being realized. The losses in textiles have received most attention and the investigations of the conditions in which cotton and wool become 'mildewed' are influencing the practices of manufacture. The methods of preserving foodstuffs—sterilization, canning, pickling and so on—are chiefly to prevent mould attack, though they also protect them from bacterial contamination.

The outward and visible sign of specific differences in fungi is morphological as in green plants and animals, but this should not mask the fact that a given species growing under definite conditions always acts in the same way and brings about the same results. Can we so harness any species that it will produce results useful to us? What has Nature herself done in this direction?

Armillaria mellea is a common toadstool which causes a good deal of disease in trees but is also able to live saprophytically. It spreads by means of rhizomorphs, strands of compacted mycelium which look somewhat like flattened, branched and anastomosing, black leather bootlaces. If these encounter potato tubers, they reduce them to mush in two or three days. On the other hand, if the rhizomorphs meet the tubers of the Japanese saprophytic orchid *Gastrodia elata*, they penetrate for only a certain distance and are then held in check. An uninfected tuber sends out a dropper and the process is repeated each year until a tuber is formed which is too small to grow. An infected tuber, however, sends out a dropper which produces an inflorescence the following year. It is obvious that the orchid obtains nutriment from the rhizomorphs, which presumably act as conducting strands. It may be that in some such reversal of parasitism we have a clue to the origin of the more typical mycorrhiza or fungus-root. Orchids are the classical example of obligate symbiosis, the seeds not normally germinating unless infected by the fungus present in certain cells of the roots. In modern methods of commercial orchid growing, either the seeds are infected artificially with the appropriate fungus, or its action is replaced by sowing sterilized seeds on a medium containing sugar.

Forest trees have a layer of fungal hyphæ surrounding many of the absorbing rootlets, the fungi concerned being mainly of the toadstool type. Many perennial plants also have mycorrhizas, but it is not yet certain which fungi are concerned: the usual appearance is suggestive of Phycomycetes. Similar associations with fungi occur throughout the plant kingdom.

The association of fungus and alga has resulted in the large homogeneous class Lichens.

Many insects have internal yeasts: indeed, these are supposed to have played a definite part in the evolution of some insect groups. A more obvious harnessing is that of the leaf-cutting ants of South America which, as first described by Bates and amply confirmed since, cultivate fungi of the toadstool type in their fungus gardens. An association in which the fungus seems to be less in subjection is that of bacteria and yeast which are active in various fermented drinks—Mexican tibi, koumiss, kephir, leben, tea cider, ginger-beer plant—some fermenting sugary liquids, others milk.

In addition to these combined masses, which are usually in the form of grains, man in his early history noted that fruit juices or other sugary fluids underwent a change if left for some time: honey-comb washings became mead, grape juice became wine. These much appreciated changes, the work of yeasts, were not to be left to blind chance, and in the course of centuries the conditions controlling the changes and finally the reason for them became known. Nowadays distillers, brewers, many wine growers and cider manufacturers no longer rely on some general supply or on casual wild yeasts, but maintain pure cultures of special strains of the appropriate species which have proved to give the best results in the conditions of production. Here we have the breaking down of organic matter by fungi to give a desired result. It must be stressed, however, that a fungus acts only in a certain way in definite circumstances.

Pasteur's classical researches on fermentation were a direct outcome of the misfortunes that befell France after the war of 1870. It is surprising how often an odd fact he mentioned more or less incidentally has been followed up by later investigations. Thus during the War of 1914–18, German scientific men turned their attention to Pasteur's observations that proteins could be synthesized by yeasts from inorganic nitrogen, including ammonium salts. The fact that yeast, including brewers' yeast, contains a high percentage of protein had long been known and attempts were made to utilize the surplus quantities from brewers until the production of beer was cut by 60 per cent. In 1915, Hayduck announced that he had discovered what he called 'mineral yeast', as a contaminant at a pressed yeast factory. This yeast, which is non-sporing and was afterwards called *Torula utilis*, gave much better yields of protein than did other yeasts and, moreover, produced little alcohol. A yeast product was put on the market, but large-scale production apparently could not be carried on because of lack of sugar.

With the outbreak of the present War, the possibility of a shortage of protein had to be faced, and the problem was allotted to A. C. Thaysen and his colleagues at the Chemical Research Laboratory. Eventually they decided that *Torula* (*Torulopsis*) *utilis* was most likely to prove satisfactory. As the situation developed, it was realized that the post-war feeding of ravaged Europe would be one of the major problems, and that for some time vitamin B deficiency would be an additional danger. An analysis of dried *Torula utilis* showed that as well as 45–50 per cent of a protein only slightly less nutritive than a good animal protein, this 'food yeast' contains the whole known range of water-soluble B vitamins. Further,

it mixes readily with water and with milk and can be used in all sorts of ways. Large-scale manufacture is to be carried out in Jamaica where molasses is abundant—200 gm. of molasses give 50–60 gm. of food yeast. The Colonial Development Fund has granted £150,000 for the erection of the plant and it is estimated that 'food yeast' can be marketed at 6*d*. per lb. Many other parts of the Empire are considering erecting plants for the benefit of the local population. It is understood that in Germany the yeast is again being used with hydrolysed wood as the source of sugar.

At Teddington, a strain of *T. utilis* was developed which will grow better at tropical temperatures than would the normal form. It gives a quicker yield and has less variability in size. Later, a giant strain (v. *major*) was produced by acting on the cells with camphor: the biochemical activities are identical, the variety is stable, its cells are more readily separable and its generative time is considerably less.

Another observation by Pasteur was that in ordinary yeast fermentation a small percentage of glycerine is always produced. During the War of 1914–18, the Germans were short of glycerol for making explosives. Neuberg, in 1911, had begun to publish his studies on the stages leading to alcohol formation by yeasts. When experimenting on aldehyde fixation with sodium sulphite, there was a large increase in the percentage of glycerol. Connstein and Lüdecke successfully applied this to large-scale production: many will remember the wild guesses that were made at the time concerning the source of the enemy's glycerine. They produced 1,000 tons a month by the method, the average yield being 20–25 per cent of the sugar used, and in addition large quantities of alcohol and acetaldehyde were obtained as by-products. It has been said that it enabled the Germans to carry on the war for another twelve months. The Americans, hearing that glycerine was being produced by yeasts, succeeded in devising a couple of similar processes. H. Raistrick and his colleagues, after 1918, used a modified sulphite process at Nobel's factory at Ardeer and increased the yields of glycerine in the fermentation liquor to 35–40 per cent of the weight of sugar fermented. Subsequent improvements in the methods of recovery of glycerine from the fermentation liquors have reduced the cost of fermentation glycerine to a figure comparable with that of soap lye glycerine.

One of Pasteur's statements, "We are convinced that a day will come when moulds will be utilised in certain industrial operations, on account of their power of destroying organic matter"*, in spite of its definiteness, was generally disregarded. However, his favourite pupil van Tieghem established the importance of moulds in the biochemical field. He investigated the method of production of gallic acid from heaps of vegetable matter containing tannin—gall nuts, sumach, tea, etc—watered and allowed to go mouldy. He showed in 1867 that the mould principally concerned is *Aspergillus niger*. The present-day method of production is to inoculate clear tannin extract with this fungus.

It was not until 1893 that the first real advance was made, when Wehmer described the production of citric acid by two species of Penicillium (Citromyces) grown in nutrient sucrose solutions containing calcium carbonate. It has been found that a number of moulds produce citric acid, but the one used on a commercial scale is *Aspergillus niger*. In 1922, Italy produced about 90 per cent of the world's supply of calcium citrate from citrous juices, but within eight years the export had practically stopped because of the commercial production by moulds—10,000,000 lb. annually in the U.S.A. alone. There is now an International Citric Acid Agreement.

The process is a surface fermentation of a nutrient sucrose solution, with a comparatively large amount of mineral acid which prevents the growth of bacteria and most moulds. The solution is seeded with spores of *Aspergillus niger*, and as these germinate the surface becomes covered with a frail pellicle which rapidly develops and, by the end of the fermentation (8–12 days), becomes a fairly thick and deeply intricately folded mat but still quite white. Most of the sugar has by then disappeared from the solution, its place being taken by citric acid practically unaccompanied by other organic acids: the solution is much more acid than good lemon juice. Some of the sugar, however, is converted into fungus starch and some into dextrin. The standard way to recover the citric acid from the fermented liquor is to add milk of lime and heat nearly to boiling point, then filter off the difficultly soluble calcium citrate and wash with hot water.

Another process in which *Aspergillus niger* is used is the production of gluconic acid, the calcium salt of which is of importance in pharmacy. Here the best results are obtained from well-aerated submerged growth, which is most economically accomplished by using rotatory drums.

Moulds are able to build up their normal cell constituents from an amazingly large and varied series of carbon compounds. Moreover, as seen with *Aspergillus niger*, the same species of mould, when growing in slightly different conditions, can produce different substances. Citric acid, oxalic acid, gluconic acid, ethyl alcohol and mannitol, which may be regarded as the breakdown products of the original sugars, are formed by many species.

There are, however, many substances which are built up by mould growth, and for the most part these are highly specific products of a single species, or of a few related species. The chief worker in this field has been Raistrick, who, following on his work on glycerol production, has been engaged with numerous collaborators in investigating the general biochemistry of moulds. The scheme followed has been to use glucose as the sole source of carbon in a synthetic culture medium—usually Czapek-Dox medium. In this long-continued and productive research, about a hundred substances previously unknown to science have been prepared and many of them synthesized. It may well be that some of these will be found useful in some way or other, but their present interest is chiefly in giving us a picture of what happens inside the cell. Mould pigments, simple quinones, polyhydroxy-anthraquinones and hydroxyxanthones, simple benzene compounds, chlorine-containing metabolic products, derivatives of tetronic acid (stimulants of bacterial growth), antibacterial and antifungal substances are included in the products*. It is a matter of phylogenetic interest that the lichen acid physcion (parietin) is formed by sixteen species or strains in the *Aspergillus glaucus* series.

To understand the magnitude of work of this kind one has to take into consideration that in a given

* "Studies on Fermentation". By L. Pasteur. English translation, 1879, p. 261. I am indebted to Dr. J. Yuill for directing my attention to this.

* A wide range of these special chemical compounds was exhibited.

species there are strains some of which are more active, some less; further, that the results differ according to the chemical constitution of the medium and the physical conditions of growth.

Ever since fungi and bacteria were grown on artificial media, it has been observed that in mixed cultures one organism may have no apparent effect on the growth of the other, or it may influence it either favourably or unfavourably. This favourable effect (synergism) may be considered as an aspect of symbiosis; the unfavourable (antagonism) as an aspect of the struggle for existence.

Antagonism is gradually becoming recognized as a factor in plant disease. The fungi which abound in the soil include some species which are able to become parasites and cause destructive root rots. Chemical and physical conditions of the soil determine the amount of a given species, but they also act on the other fungi present, one or more of which may have an antagonistic reaction towards the parasite. Thus the mould *Trichoderma viride*, common in the soil, has an antagonistic effect on the growth of the tree parasite *Armillaria mellea*.

The phenomenon of antagonism has been brought strikingly to public notice following an observation by A. Fleming in 1928. When studying the growth of Staphylococcus on solid media in Petri dishes, he noticed that the colonies underwent lysis in a zone surrounding a growth of Penicillium which contaminated one of his cultures. He grew the Penicillium in broth culture, and found that the filtrate was some two or three times as effective as pure carbolic acid in stopping the growth of Staphylococcus.

For convenience the name 'penicillin' was used in place of the rather cumbersome phrase 'mould-broth filtrate'. Fleming showed that penicillin had a specific action on certain bacteria (Staphylococcus, Streptococcus, Pneumococcus, Gonococcus and the diphtheria bacillus), but that others (*B. coli* and *B. influenzæ*) were not affected. The first practical application of penicillin was the isolation of the insensitive Pfeiffer's bacillus, which in the respiratory tract is usually associated with organisms highly sensitive to penicillin. But Fleming also stated that penicillin had no poisonous effect and that "it may be an efficient antiseptic for application to, or injection with, areas infected with penicillin-sensitive microbes". In 1931, he prophesied that "it is quite likely that it, or a chemical of a similar nature, will be used in the treatment of septic wounds". In the following year Raistrick and his collaborators grew the Penicillium (which Thom identified as *P. notatum*) in a synthetic medium consisting solely of glucose and inorganic salts, and defined the optimum conditions of growth. They acidified the medium slightly, extracted with ether, and on removal of the ether obtained the anti-bacterial substance in a crude form and to it restricted the name penicillin. It was found to be extremely labile. A very definite step had been taken* and sulphonamides were not yet discovered. It remained for H. W. Florey and his collaborators to reveal the outstanding therapeutic properties of penicillin. Florey worked first with lysozyme, another of Fleming's discoveries, and in the search for other anti-bacterial substances produced by micro-organisms, E. Chain and Florey turned their attention to penicillin. A culture of Fleming's fungus was obtained and the penicillin was extracted with amyl acetate. Shaking out the amyl acetate with a buffer solution and evaporating the buffer solution gave a substance which was at first thought to be pure penicillin because it proved to be so active. The results of the clinical trials published in 1940 showed that it possesses unique therapeutic properties which, moreover, because of its non-toxicity, make it of outstanding value in the treatment of war wounds. But the penicillin used in these chemical experiments was only about 1 per cent pure. Several workers here and in the U.S.A. are engaged on research in purifying penicillin; a crystalline sodium salt has been obtained which is substantially pure and is a hundred times more active than the first extractions. It is capable of inhibiting the growth of certain bacteria at a dilution of about 1 : 50,000,000. Penicillin is a complex acid of which the exact structure is not yet known.

Until recently, all the *Penicillin notatum* used, both in the laboratory and in large-scale manufacture, was from Fleming's original isolation. It was indeed a strange chance which led to the contamination of a laboratory culture by an apparently uncommon mould (originally described from decaying hyssop in Norway); and that the laboratory should be that of one who was curious in antibiotic phenomena and who, convinced of the value of his discovery, kept not only the original plate but also maintained the mould in culture. Further, it was fortunate that the original Oxford isolation of crude penicillin contained little if any toxic substances, with the result that Florey and the Oxford team were so soon able to announce almost undreamed-of achievements. This general freedom from association with harmful products incidentally has also characterized 'home-grown cultures' of penicillin.

Penicillin is the most active bacteriostatic substance so far known; but the difficulty of obtaining sufficient quantities and its unstable quality have led to the search for similar mould products, and has also stimulated general research. There are many such products known, but few are sufficiently non-toxic for use. Flavicin from *Aspergillus flavus* and gigantic acid from *A. giganteus* are most similar to penicillin in their chemical and biological properties.

Raistrick and his colleagues have tested many of the compounds they had isolated and all new substances which were obtained. The product of the fermentation of *Penicillium patulum* (originally isolated from sheep dung in France) was considered promising and was sent to W. E. Gye, who is studying the effects of various substances on cancer cells. As he was suffering from a cold, he used it on himself with most satisfactory results. Extended trials show that it is able to cure a promising number of cases of one form of the 'common cold'. It has since been shown that patulin is identical with clavacin and clavatin obtained from *Aspergillus clavatus*, and claviformin, from *Penicillium claviforme* and *Aspergillus giganteus*. It is not surprising that the same chemical substance should be formed by several fungi —indeed, this is what one would expect. What is of greater interest is that it is also produced by *Penicillium expansum*. Van Luijk in 1938, studying the diseases of grasses caused by species of Pythium, found a difference in plants grown in sterilized and non-sterilized soil. He isolated a number of fungi

* "Another point which shows what practical results may be expected from such research is that penicillin, a metabolism product of *Penicillium notatum* is non-irritant and non-toxic, but has a strong though differential antibacterial power." Presidential Address to Section K of the British Association, Ann. Rept. Brit. Assoc., 1936, p. 215.

from the soil and from the air and tested their influence on the growth of Pythium. He found that *Penicillium expansum* was the most markedly antibiotic, and adopting Fleming's procedure, obtained sterilized filtrates: these inhibited the growth of *Pythium debaryanum* at dilutions of 1 : 1,280. He did not isolate the antifungal substance, which Anslow, Raistrick and G. Smith (1943) have shown to be patulin. When the fungus was added to garden soil infected with Pythium, seedlings remained healthy instead of damping off.

Here we seem to have a linking up of different lines of research in such a way that we may expect considerable progress. The recognition of the chemical constitution of a substance produced by a common soil fungus which suppresses the growth of a plant pathogen suggests that greater precision may soon be given to many of the older observations on fungal antagonism of various kinds. Incidentally, it may also have some bearing on the question of natural compost versus chemical fertilizers. There is a difficulty in establishing the growth of antagonistic organisms in the soil; this can be done only by modifying the conditions, and an obvious way to do this is to add manure or compost which favour fungal growth. That the matter is not quite so simple as it appears at first sight, however, may be judged from the fact that Barnum in 1924 showed that the filtrate of cultures of *Penicillium expansum* caused wilting in certain herbaceous plants placed in it.

No more than mention can be made of the production by fungi of fats, ethyl alcohol, lactic acid, vitamins, and enzymes, or of the immense fermentation industries of the Orient.

PLASTICS AND ELECTRICAL TECHNOLOGY

PLASTICS and electrical technology are close allies on the industrial front, with many points of contact, and in recent years meetings have been arranged at which members of the two professions can exchange views and comments on recent developments of common interest. The latest meeting of this kind, arranged by the Plastics Group of the Society of Chemical Industry, was held at the Institution of Electrical Engineers on April 14, when the topics selected were the electrical properties of the newer thermoplastics, radio-frequency heating, and 'tracking'.

In opening the discussion, Mr. H. A. Nancarrow pointed out that in the pure hydrocarbon thermoplastics, poly-ethylene, poly-*iso*butylene and polystyrene, we have arrived at the almost perfect dielectric, in the sense that their power factors are almost vanishingly small, over the entire range of frequency and temperature encountered in electrical practice. In these materials we have the excellent qualities of pure paraffin wax associated with a wide range of mechanical qualities from great flexibility to brittleness. The power factors of the pure materials are, generally speaking, of the order of 0·0003. Much higher values are sometimes quoted, but they are usually due to impurities; either plasticizers added to facilitate extrusion or moulding of the material, or oxidation products, produced when the material has been overheated in air. These materials have made possible many developments in electrical communication at the highest frequencies, where even the smallest power factor, or power loss per cycle, may be very significant. At lower frequencies where higher power factors can be tolerated, thermoplastics like poly-vinyl chloride, which is doing valuable service as a rubber substitute in power cables, and polymethyl methacrylate, well known as 'Perspex', are being widely used. The power factors of these materials are of great scientific interest. They show the characteristic of all polar materials—a high maximum value at a particular frequency or periodic time corresponding with the relaxation time of the molecule. The work of Fuoss and other workers in America on the effect of plasticizers on this molecular relaxation was reviewed, but the discussion showed that though the spade work is progressing well, it has not yet reached the stage where important generalizations are possible.

In opening the discussion on the second topic, Dr. L. Hartshorn remarked that it has recently received a great deal of publicity under such very questionable terms as 'radiotronic' heating and 'heatronic' processes. These newly coined terms seem to be entirely unnecessary. The term 'radio-frequency heating' is satisfactory, but it includes eddy-current heating of metals at radio-frequencies, as well as that of plastics and other insulating materials by the process under discussion, which Dr. Hartshorn suggested should be called 'dielectric heating'. The meeting appeared to be prepared to accept the suggestion. The basic facts have long been known. Any solid or liquid insulating material placed near a conductor which is maintained at a high alternating voltage of high frequency becomes more or less hot. The heat is generated throughout the whole mass of the material, the rate of conversion of electrical energy into heat in any element of volume being proportional to the square of the electric field-strength in that element. The basic experimental facts were forced on the attention of radio engineers in the earliest days of high-power wireless transmitters: insulating supports frequently became so hot as to catch fire, and much research has been needed to discover materials like the pure hydrocarbons discussed by Mr. Nancarrow in which the development of heat is as small as possible, and those which will resist better the action of the heat that is developed. The new ceramic materials are of this class.

The idea of utilizing this generation of heat for industrial purposes seems to have originated in various quarters about fifteen years ago, though it has only quite recently been put into practice on any extensive scale. American patent literature from 1930 onwards describes various schemes for using dielectric heating for sterilizing milk and other foods, killing pests in plant bulbs, drying artificial sponges and tobacco, cementing plywood and safety glass, and leather soles on to shoes, and so on. At first sight it seems curious that the method is still a novelty in industry; no doubt economic factors as well as the technical difficulties have played their part here.

The importance of the process lies in the fact that it makes possible the rapid and uniform heating of thermal non-conductors of any thickness. In a large American plant stacks of plywood 1 ft. thick are said to be heated through a temperature range of 160° F. in five minutes, this rise of temperature being required for the setting of the urea-formaldehyde glues employed in the making of the plywood. The method has also proved valuable in the plastics

industry for the heating of moulding materials as a preliminary to moulding. The uniformly heated material flows better into the mould and gives a more uniform moulding than material heated by a contact method, while the rapid heating reduces the time required for the complete moulding process.

An attractive feature of the process is that it makes possible the selective heating of a mixture or composite structure. Thus in fields of a given strength and frequency, the rates of generation of heat in different materials are proportional to the product of their dielectric constant and power factor. The power factor of plate-glass is very small and almost invariable over the whole range of radio frequencies ; that of cellulose acetate rises to a high value at a frequency of the order of 10 Mc./s. Thus if alternate layers of plate-glass and cellulose acetate are placed in a high-frequency electric field, the plastic will generate sufficient heat to be brought to the softening point while little heat is generated in the glass. The prospect of facilitating the manufacture of safety glass in this way is one of the most attractive features of dielectric heating.

Among plastics it seems likely that the process will be limited to materials which show an absorption band, that is, a more or less sharp maximum power factor in the radio-frequency range : other materials would require excessive voltages in order to generate sufficient heat. Thus the heat may be considered to originate in oscillations of the polar groups of the materials under the action of the alternating electric field. The question was raised : Is it possible that such heating at particular frequencies may be associated with special chemical activity, and therefore be of special value in processes like the curing of resins ? There appears, however, to be no evidence to suggest that such processes are stimulated by an electric field and selective as to frequency.

The advantages that may be gained by dielectric heating are so great that it may well revolutionize many industrial processes. It is, however, necessary to recognize that it has its limitations. First, as a method of generating heat it is bound to be expensive. In order to get the energy into the form of a high-frequency electric field, it must go through various transformations : low-voltage A.C. to high-voltage A.C. ; then to high-voltage D.C. via rectifiers ; then via thermionic valves to the final form. Each transformation requires equipment which may be expensive, and valves being high-resistance generators necessarily involve considerable losses of energy. The result is that dielectric heating cannot compete with ordinary electric heating (conductor heating) or steam heating for processes in which these are effective and not unduly slow. There is also the difficulty of avoiding interference with radio communication. This can, of course, be done by adequate screening, but this adds to the cost and may limit the ease of operation of the process.

A more fundamental limitation arises from the fact that the conditions for uniform heating are not always easily realized, and when uneven heating occurs there may be a risk of damaging the material. There is no maximum temperature which cannot be exceeded, like that of the steam in steam heating. In certain conditions the process is an unstable one. Thus if, as is not uncommon, the dielectric constant and power factor of a material increase with rise of temperature, then the effect of a rise of temperature is to increase the rate of heating, so that the action is cumulative. If this occurs throughout the mass, it will become obvious and the voltage will be reduced either by the operator or automatically as the heating proceeds. But if it is local, it may be undetected since it is the interior of the material that is usually hottest. Obviously then the material to be heated must be carefully controlled as to its uniformity and dielectric properties. Uniform heating will then be obtained provided the electric field is uniform. This again is not always a simple matter. A uniform field can be obtained between two plane parallel electrodes large in comparison with their distance apart, but as the distance apart increases in relation to the size of the plates there is a concentration of field near the surface of the metal. Occasionally this may be useful in counteracting the cooling effect of the electrodes ; but in other cases it is necessary to have an air gap between the material and the electrodes to avoid excessive heating of the surface layers.

There can be little doubt that the process will lead to important developments in plastics technology. The ability to heat large thicknesses uniformly makes possible the manufacture of laminated material such as is used for gear wheels in thicknesses previously unknown, and should make possible the production of thicker mouldings. The rapid jointing of materials like leather and fabrics with thermoplastic cements should be possible for sheets of any thickness, while the welding of thermoplastics of any thickness also becomes a possibility. The search for plastics of low power-factor which has had such striking successes in recent years may now be followed by one for materials of very high power-factor in some particular frequency range specially suited to dielectric heating.

The last subject discussed was the breakdown of insulating materials by the process technically known as 'tracking'. This is a localized, but progressive, charring, which, starting at one point, spreads more or less rapidly as a tree-like growth right across the surface of the insulator, finally short-circuiting it and carrying so much current that the insulator is destroyed by the heat generated. In opening the topic, Mr. E. Rushton explained that it is essentially a surface phenomenon, which only takes place on insulators which have been in service for some time, and only occurs in a humid atmosphere. That it is a surface phenomenon is shown by the fact that it can be to some extent prevented by coating the surface of the insulator with special varnishes, but there are the most diverse views as to the nature of the process, and correspondingly diverse opinions about suitable tests for the grading of materials for their tendency to fail by tracking.

It is generally agreed that the phenolic resins are on the whole more liable to fail in this way than urea resins, and it was stated that melamine resins are even better than urea ones in this respect ; but it was suggested that the difference is more likely to be one of macro-structure than molecular constitution. The final stage of the process is clearly dependent on a heterogeneous surface structure ; but how far this is characteristic of the resin itself and how far dependent on the chemical effect of surface moisture under the sustained voltage gradients in the surface is still a matter of conjecture. Stäger has described the process as analogous to the fatigue corrosion of metals, and dependent on the salt content of the materials, which gives rise to mobile ions in the films of water on the surface in a humid atmosphere. These ions moving under the action of the surface

voltage gradients lead to local deposits of salt and local concentrations of field strength, and therefore to local heating, which starts the formation of a conducting track of carbonized material. Once it has started it will inevitably travel down the voltage gradient, for it will behave like a pointed conductor at the tip of which there will always be a strong concentration of field strength and therefore local heating when the surface conductivity is appreciable.

Another view put forward was that tracking is always started by sparking over the surface, the steep voltage gradient required to produce a spark arising where the surface of the insulator becomes partially bridged by patches of relatively high conductivity, leaving narrow gaps of low conductivity to support an undue share of the total voltage. The conducting patches may arise from dirt or irregular wetting as the humidity rises.

Tracking can certainly be deliberately initiated by applying a high voltage and so causing sparks to pass over an insulating surface between electrodes with sharp edges, or alternatively by spraying the insulating surface with salt solution and so causing irregular wetting while a comparatively low voltage is applied; and these methods are used as rapid tests of the tendency of materials to break down by tracking. Their reliability as an index of performance in practice is not, however, universally conceded. A quick test would be of great practical importance in the development of 'anti-tracking' plastics, but a controlled procedure which will reproduce accurately the essential conditions will only be possible when the phenomenon is better understood.

Dr. Haefely somewhat ruefully summarized the immediate practical results of the meeting by saying that, as a manufacturer, he would, under present conditions, have to continue to make the best materials he could, to wait for apparatus for dielectric heating, and to design his electrodes so as to discourage the initiation of tracking.

L. HARTSHORN.

SCIENCE AND ART AT THE ROYAL ACADEMY, 1944

By DR. A. T. HOPWOOD
British Museum (Natural History)

IN 1942 I attempted[1] to explain what I understand art to be. Since some of my gossips later took me to task because neither beauty nor truth were mentioned, it may be well to point out that beauty is not essential to a work of art, and that truth is an ambiguous word often used to mean accurate representation.

Consider, for example, the numerous flower pieces in the present Royal Academy Exhibition; these range from highly finished coloured drawings to mere blobs of paint placed in such a way as to give the impression of flowers. A botanist or a gardener will probably prefer the former, since the flowers are easy to identify, and that makes for self-confidence in the observer, who feels that he understands what the painter is trying to do, though whether that feeling is justified is perhaps another matter. An artist, on the other hand, may well prefer the blobs; he thinks more in terms of harmonies, contrasts and design, and notices how the whole is enlivened by discreet touches of discordant colour, and how by proper emphasis the whole thing is made to hang together. In the popular sense of the word, only the first type of painting is true, whereas in fact both are true. Provided that this ambiguity is recognized, one is justified in the claim that truth is an essential component of art; but it was to avoid any misunderstanding that I spoke of intellectual honesty instead.

With so high a standard in the exhibits, the critic this year is fortunate in his lot. There are numerous items to which one would like to direct attention, but most of them are excluded by the title of this notice. Of those which remain, pride of place must be given to "Night Raid, 1941" by Richard Eurich (No. 710). Although it was painted "for the Nation's War Records", this work has about it a quality which lifts it above the competent journalism of the average war reporter. The canvas is full of incident, it tells not one story but many; the contrast between the hot fiery glow and the cold glare of the searchlights is admirably handled, but the hard white mount is not so well inspired. More than all these is a quality of innocence, as though the artist had approached his subject with the unspoilt mind of a child and recorded the night's events with a simple directness which more sophisticated minds would label primitive. "Antwerp" (No. 17) by the same artist is in a different mood; it was painted before the War began and is one of the Chantrey Bequest purchases; good picture though it is, "Night Raid" is better.

In so far as it is possible for one artist to steal the show, that has been done by A. R. Thomson. Look at his two pictures, "Apple Trees" (No. 97) and "Miss Joan Chapman" (No. 102), which hang a few feet apart in Gallery II. The trees really grow out of the grass; the spraying and the pruning may have been neglected, but the whole picture is redolent of the average farmer's orchard. In complete contrast is the relaxed body of the dancer, whose weight is taken down well and truly to the right foot. Then go round the corner and read the character of the chairman of the London County Council in his portrait (No. 224), and, finally, look at the young airmen having a happy night in the mess before "Going to be Decorated" (No. 754). Such versatility does not appear very often.

As for the purely scientific aspects of the Exhibition, the anatomist should enjoy the portrait of Miss Chapman just mentioned, and medical men Nos. 292 and 746—the titles are too long to quote. The portrait of Sir Henry Dale by Francis Dodd (No. 140) is not convincing, and that of Sir John Russell by Francis Hodge (No. 335) is irritating because the direction of the sitter's gaze, towards the bottom left corner of the frame, continually leads one's eyes away from the centre of the picture and distracts the attention. Here, too, may be mentioned Francis Dodd's charcoal drawing of Sir Charles Sherrington (No. 977) and Alfred Hardiman's bronze, "Study of a Scientist" (No. 1177).

Zoological subjects are few; most of them are horses which, apart from those by A. J. Munnings, P.R.A., are not particularly good. The best is the group to the right of the centre in Munnings' "Winter Meeting" (No. 17). Not only does the necessary foreshortening pose a difficult problem in perspective, but also the design made by the animal's feet is well-conceived; moreover, the horse and its rider are full of life and motion. One of the most curious

paintings is "Bringing up the Horses" by James Bateman (No. 169), in which the dark horse is so good whereas the grey is a pantomime 'prop'. In the Sculpture Gallery, "Shire Horse" by Barbara Waller (No. 1237) is conventional, but still a Shire. "Gazelle" by Alfred Oakley (No. 1243) is also conventional, with horn-buds more closely resembling those of the red deer than those of a gazelle.

Since the entomologist rarely has anything of his own, he may care to look at "Butterfly Tree" by Constance Stallard (No. 867). Neither the butterflies nor the shrub will cause him any difficulty.

Among the pictures of birds are, "Chinese Geese" by Jessie Hodge (No. 566), "Solway Company" (No. 900), "Geese and Mallow" (No. 903), and "The Covey" (No. 904), these last by C. F. Tunnicliffe. All four are illustrative of the difficulty of dealing with pictures of 'scientific interest', for they are so close to Nature that the slightly conventional drawing and not quite accurate colouring are apt to be disturbing rather than sympathetic. That painters approve of them is shown by the fact that Mr. Tunnicliffe's drawings have been purchased out of the Stott Fund, whence one may conclude that the fault lies with the critic and not with the artist.

Another type of problem is afforded by the work of Sidney Lee. This artist's favourite colouring, which inevitably brings to mind the old jingle "Greenery yallery, Grosvenor Gallery", is admirably suited to work in the Pennines—"Over the Hills" (No. 138)—but it does not carry conviction elsewhere, even when, as in "Thun" (No. 109), it is used with caution. Algernon Newton seems to have a similar difficulty: his canal scenes are among the very best of their kind, but when he tries to render "A Yorkshire Landscape" (No. 488) or "September" (No. 483) with the same palette the results are deplorable.

Much good work is to be found in the room devoted to black and white, including a number of architectural subjects. The fact that duplicate prints are often obtainable, with a corresponding increase in the number of red stars on the frame, enables one to estimate the public taste. This year the very attractive "Jenny Wren" by Winifred Austen (No. 1055) is without doubt the most popular.

The Architectural Room is dominated by the immense "Plan of London Communications" which ought to have a special note to itself. Suffice it to say here that, by an ingenious planning of the roundabouts, pedestrian, slow and fast traffic are all kept apart and that, to quote its authors, "the leisurely and carefree conditions of the old market place have been restored, though developed and improved to suit modern life". From the market place one's thoughts turn naturally to the home, only to be disappointed. Two years ago I protested against some houses designed for erection in the Wirral. Since then they have been built and photographed, and their photograph hangs on the Academy wall (No. 1106), to prove that for depressing ugliness there is nothing to surpass them in the back streets of Manchester or Leeds. To the various authors of these and other plans (Nos. 1098, 1102, 1111, 1117) may be recommended the wise words of the Royal Academy Planning Committee, "It is important to avoid the mechanistic character of extreme modernism, with its soulless or even frightening aspect of the merely functional. A more human and friendly character is required for the surrounding scene of the people's life and business."

[1] NATURE, 149, 603 (1942).

OBITUARIES

Dr. C. B. Davenport

DR. C. B. DAVENPORT, who died on February 18 at the age of seventy-seven, was one of the pioneers of genetics in the United States. He was born at Stamford, Connecticut, in 1866, and graduated from Brooklyn Polytechnic at the age of twenty. From then until 1899 he was associated, in various capacities, with the Zoology School at Harvard. In 1899 he moved to Chicago, only to return east in 1904 on his appointment as director of the Carnegie Institution Station at Cold Spring Harbor. It is in connexion with this Station that Davenport will be mainly remembered, for he remained there some thirty years until his retirement, and left it occupying the position of one of the leading centres of genetical research in the world.

An interest in natural variation developed early, and in 1899 we find Davenport publishing a small book, "Statistical Methods", where he outlined the biometrical approach to the collection and analysis of data on variation. With the rediscovery of Mendelism, however, fresh possibilities opened up and he began extensive investigations along these new lines using a variety of animals, especially poultry. The poultry experiments demonstrated Mendelian inheritance for many characters, though with complications in some cases. The results were published largely in the form of two extensive papers, dated 1906 and 1909, in the Carnegie Institution series. It is of interest to note that in the 1906 publication data are reported, from the F_2 of a cross between single-combed Black Minorca and white-crested Black Polish fowls, which supply evidence of linkage between the gene for crest and cerebral hernia on one hand and that for split and reduced comb on the other.

The application of genetics to man also attracted Davenport's attention, and in 1911 he published "Heredity in Relation to Eugenics". In this book is discussed the inheritance of a great variety of human traits from eye-colour, hæmophilia and cancer to insanity, criminality and pauperism. The hereditary aspect is brought out in all cases, though only in some of them do the data indicate a simple type of inheritance. The implications of these findings are discussed at some length in relation to migration (then a most active problem in the United States), sterilization, segregation of the unfit and so on. This interest in human heredity loomed even larger in Davenport's later work, when we find him writing on sex-linkage in man, the inheritance of twinning, the genetical factor in endemic goitre, crime in relation to heredity and other topics of the kind. His interest in the biometrical technique seems also to have at least partially revived in later years.

Davenport occupied a prominent position in contemporary American biology. He was a member of the National Academy of Sciences and served on the editorial boards of a number of scientific journals, notably *Genetics* and the *Journal of Experimental Zoology*. Of the many societies and associations to which he belonged those concerned with eugenical questions form a large part, and his work in this field was appropriately recognized in 1932 when he was made president of the Third International Congress of Eugenics, held in New York.

K. MATHER.

Prof. W. M. Thornton, O.B.E.

WILLIAM MANDELL THORNTON was born in Liverpool in 1870 and had his schooling at the Liverpool Institute. After eight years of practical work with an engineering firm he entered the University College (now the University) of Liverpool, where he worked under Lodge and Carey and graduated in the honours schools of physics and engineering. He was senior lecturer in engineering in the University of Bristol during 1896–98, lecturer in electrical engineering in Armstrong College (now King's College), Newcastle upon Tyne, from 1898, and was appointed to the chair of electrical engineering when this was inaugurated in 1906. On retiring from the chair in 1937, he was elected professor emeritus of the University of Durham.

Thornton took a lively interest in the work of the Tyneside engineers and was elected chairman of the North Eastern Centre of the Institution of Electrical Engineers for the year 1905–6 and again for 1921–22. He was president of the Association of Mining Electrical Engineers in 1920–21 and president of the Institution of Electrical Engineers in 1934–35. In 1920 he was decorated with the Order of the British Empire, and more recently the Greenwell Gold Medal was conferred upon him by the North of England Institution of Mining and Mechanical Engineers for his researches on gaseous and dust explosions in mines.

An account of Thornton's achievements is an indication of the scope and fervour of his mind ; so too are some ninety original papers which he contributed to the scientific and engineering journals. His thought moved naturally in terms of physics and mathematics, but his early training taught him to understand the problems of practising engineers ; and his great humanity made him eager for the vigorous growth of applied science. His research on gaseous and dust explosions, the work for which he is perhaps most widely known, had its inspiration in a visit which he paid to a colliery where an explosion had occurred. The damage and injury which he saw made an impression which was never obliterated. He described his feelings recently when speaking of it—"Surely we should be able to prevent this". The work he extended later at the suggestion of the Institution of Electrical Engineers and the Medical Research Council with the object of increasing the safety in operating theatres where ether is used as an anæsthetic.

Thornton also investigated with enthusiasm the problems of high-voltage measurement, the operation and design of electrical machines, the theory of dielectrics and the electrical conductivity of bacteria. During his last illness he looked forward constantly to his return to the laboratory.

It is not surprising that as a teacher Thornton could bring to his students the feeling that new discoveries were always within their reach, and, guided by him, undergraduate and postgraduate investigation flourished. His zest for research and his delight in discovery were at once apparent ; you went further and knew that the happiness which he communicated arose from something deeper than an untiring intellectual appetite, and that in him the whole man was happy because grounded upon a confident faith.

In spite of his many preoccupations Thornton was always accessible : always ready to listen and understand. All who knew him were proud to feel themselves his friends. "Few, in general estimation, are sincerely praised : few can evoke both wide and deep affection." Of these few Thornton was one.

J. C. PRESCOTT.

Dr. E. C. Scott Dickson

DR. E. C. SCOTT DICKSON, senior lecturer in physics in the University of Manchester, died at his home in Manchester on April 8.

Younger son of Lord Scott Dickson and nephew (by marriage) of Sir James Dewar, Dickson was born at Edinburgh in 1888. He was educated at Edinburgh Academy and Trinity College, Cambridge, where he took the Natural Sciences Tripos. Later he proceeded to the University of Bonn, and worked under Prof. Kayser for two years, taking a Ph.D. degree for research on the ultra-violet fluorescence of the benzols. In 1913 he was appointed demonstrator in physics in the University of Toronto. During the War of 1914–18 he served in India and in Mesopotamia with a battalion of the Highland Light Infantry.

In 1919 Dickson was appointed to a lectureship in physics in the University of Manchester, and continued his work there under Prof. W. L. Bragg and later Prof. P. M. S. Blackett until his death.

During his earlier years at Manchester, Dickson took part in the research work on crystal structure problems under Bragg. But his chief work in Manchester, for which he will be remembered, was as a physics teacher particularly of elementary students. In recent years he had charge of the physics teaching of medical students, and he organized this with characteristic thoroughness and keenness. He gave much time and thought to their interests and was always on the look-out for new ways of interesting medical students in physics and its applications to medicine. Apart from being an able physicist, Dickson had a very wide range of interests. He was exceptionally keen on music. During his student days in Germany he studied singing seriously with an intimate friend of Brahms. At Manchester he took particular delight in giving a special course of lectures on acoustics to a small group of students preparing for the Mus. Bac. degree. He was interested in all the arts and convinced of the value of classics in education, even for scientific men.

On the routine side of the work of the University, Dickson was a valuable member of the Faculty of Science and of the Faculty of Music. His loss will be particularly keenly felt during the period of reconstruction after the War, when such an experienced and wise university teacher and administrator as was Dickson would have rendered invaluable service.

J. M. NUTTALL.

WE regret to announce the following deaths :

Prof. W. E. H. Berwick, emeritus professor of mathematics in the University College of North Wales, Bangor, on May 13, aged fifty-five.

Mr. H. N. Dixon, the distinguished bryologist, on May 9, aged eighty-three.

Prof. Edward B. Mathews, emeritus professor of mineralogy and petrography at the Johns Hopkins University, on February 4, aged seventy-four.

Lieut. G. B. Wilson, information officer, South African Army, formerly director of the Rhodes-Livingstone Institute of Anthropology, Northern Rhodesia, aged thirty-five.

NEWS and VIEWS

Regius Chair of Zoology, Glasgow: Prof. C. M. Yonge

PROF. C. M. YONGE, professor of zoology in the University of Bristol, whose appointment as regius professor of zoology in the University of Glasgow is announced, is one of the most distinguished of the younger British zoologists. Receiving his early training at the University of Edinburgh, he has devoted himself for the last twenty years to the study of the interrelated physiology and morphology of marine animals, especially corals, molluscs and crustaceans. Beginning with his memoirs on the physiology of digestion in Mya (1923), Nephrops (1924) and Ostrea (1926), he has published a long series of admirable papers on the functional morphology of the Mollusca, and later on the remarkable functions of chitin and cuticle in the Crustacea, in relation to moulting and oviposition. His work on corals and their enclosed zooxanthellæ dates from his participation as leader in the Great Barrier Reef Expedition during 1928–29, and was later continued at the Tortugas Laboratory of the Carnegie Institution. In all these studies, his interest has lain in function and adaptation, in the activities of the living animal in relation to its structure and its environment, and he has been at pains to link up physiological and morphological facts. He takes a biological, rather than a physiological or morphological, view of the living animal, thus adding greatly to the significance and interest of his results. In the course of his studies he has travelled widely, visiting many of the principal marine biological stations throughout the world.

In addition to his scientific papers, Prof. Yonge published in 1930 "A Year on the Great Barrier Reef", and collaborated with Mr. F. S. Russell in "The Seas", a fascinating introduction to marine biology. He is an active member of the Development Commission's Advisory Committee on Fishery Research and of the recently appointed Committee on Post-War Fishery Research. While professor of zoology at the University of Bristol, a post which he has filled since 1933, he has been successful in stimulating research by his staff and students, promoting in recent years a co-operative study of the biology of the Bristol Channel. There is no doubt that he will be equally successful at Glasgow, especially with the facilities of the Millport Marine Biological Station close at hand.

Medical Services for India

FOR his address delivered at the Founder's Day Celebrations of the Lady Hardinge Medical College for Women, New Delhi, on March 17, Major-General J. B. Hance, director-general of the Indian Medical Service, took as his subject the need in India for a rapid and wide development of medical services, and he discussed the part which women will play in it. His address may be compared with Dr. Krishnan's presidential address to the Section of Medical and Veterinary Sciences at the Indian Science Congress held in January (see p. 658 of this issue). There is now, said General Hance, complete agreement throughout the world that health is a basic human right. Outlining the conditions required for 'positive health', he said that it is the goal of Indian medicine to provide these for every man, woman and child in India. The task is, as he and Dr. Krishnan clearly show, a formidable one; but it is no less evident that no responsible authority in India is going to shrink from it. The basis of the effort must be, General Hance emphasized, not this or that political philosophy, but "the united and indomitable will of the whole people to place their country on the map of modern civilised progress". Like Dr. Krishnan, he referred to the medical progress made in the U.S.S.R. during the last twenty years and he insisted that this has not been due to the Marxian philosophy, but to the united will of the Russian people. Nor need the cost of the effort required be a deterrent, for Lord Keynes and Prof. A. V. Hill, secretary of the Royal Society, have both reminded us that money is the servant and not the master of policy. The Allied war policy has proved that this can be so, for, if money had governed the prosecution of this War, hostilities would have ended long ago in the victory of the immensely superior financial resources of the Allies.

Certainly the figures quoted by both General Hance and Dr. Krishnan prove that India's medical needs are great and urgent. A nation should have, General Hance said, a minimum of one doctor to every 1,500 of the population. The United Kingdom has one to every 1,000. India has one to every 10,000; it has 40,000 registered doctors to-day and requires 300,000. A similar need of nurses, health visitors, midwives, pharmacists and dentists indicates the magnitude of the task which faces Indian medical education, and this is only part of the whole problem. General Hance stressed the need for emphasis on preventive and social medicine. Tuberculosis is an urgent special problem in India as elsewhere, and half a million beds are required for tuberculous Indians, at least half of whom are women. The care of the blind, of whom there are some two and a half million in India, is another great task. Industrial medicine will become more and more important in India with the increasing pace of industrial expansion. Research and teaching are also essential and must be carefully developed and fostered. For all these tasks the services of medical women will be required and for some of them they are essential. There is a great and inspiring future for the young medical men and women of India to contemplate. There are, as General Hance said, many eager and capable hands reaching out to take up the torch handed on by their elders. They will, as they look out from India over land and sea, be inspired by the similar noble work being done by their fellow workers near at hand in the U.S.S.R. and China and farther away in the Americas. The busiest of them all in the next decade will be those who must work in the suffering lands of a Europe freed at last from famine and war.

Institute for the Study of Animal Behaviour

AT a meeting of the Council of the Institute for the Study of Animal Behaviour held on April 20 two new members of Council were co-opted. The full Council is now: Dr. E. S. Russell (*president*), Dr. R. J. Bartlett, Dr. R. W. Douglas, Dr. J. T. Edwards, Mr. James Fisher, Dr. E. Hindle, Dr. Julian S. Huxley, Mr. F. B. Kirkman (*hon. treasurer*), Dr. W. H. Thorpe, Dr. Arthur Walton, Mr. Alastair N. Worden (*hon. secretary*), and Prof. S. Zuckerman. Arrangements were made to publish a new number of the *Bulletin of Animal Behaviour*, and speakers were chosen for the joint meeting to be held with the Royal Society of Medicine (Section of Comparative Medicine) on June 21, as follows: Dr. C. S.

Myers (instinct), Dr. W. H. Thorpe (learning processes in animals), Dr. F. B. Kirkman (bird behaviour), Prof. D. B. Johnstone-Wallace (grazing habits of beef cattle), and Dr. Arthur Walton (comparative sexual behaviour in the male). It was agreed also that Prof. Samson Wright and other psychiatrists should be invited to speak at this or a succeeding meeting. Future research projects were discussed, especially those in the veterinary field; for example, the individual behaviour of various domestic species, the grazing habits of sheep and cattle, and the utilization of behaviour reactions in supplementing clinical, pathological and biochemical studies of domestic mammals. Certain ornithological studies, suitable for members, were also discussed. It was decided to circulate these projects at an early date. Consideration was given to the matter of research grants, and it was agreed to take steps to try to secure funds for specific observational studies involving domestic animals. Membership of the Institute is open to all interested persons. The annual subscription (12*s.* 6*d.*) includes payment for the *Bulletin of Animal Behaviour*. Communications should be addressed to the Hon. Secretary, Institute for the Study of Animal Behaviour, c/o Zoological Society of London, Regent's Park, N.W.8.

The War-time Social Survey

A PAPER on the "War-time Social Survey" was read at a meeting of the Royal Statistical Society on May 16 by Kathleen Box and Geoffrey Thomas. The War-time Social Survey is the Government social research unit, and has been set up to provide any department with information, needed for the planning and administration of policy, which is not available from other sources. It is concerned with social problems, in the investigation of which it aims at establishing facts and attitudes of the public towards these facts. The method used to achieve these ends may be described briefly as interviewing samples of the general public, or of particular sections of the general public, with a recording schedule devised so that the results of the inquiries made can be expressed statistically. Investigations are carried out by fifty-five trained fieldworkers, all women. The reception accorded to fieldworkers suggests that the public is ready to appreciate the importance of such inquiries and to give all possible help. The proportion of people eventually refusing to be interviewed is about 0·5 per cent in most inquiries. The Survey has had to rely very largely on devising its own techniques for different occasions as they arose. The experience gained by other workers in the field of social research, both in Great Britain and in the United States, has been used, and most members of the research staff, coming as they do from different organizations which have been doing allied work for many years, have had different contributions to make.

The Survey can provide a closer link between the administrator and administered than is normally possible, particularly in relation to the preparation and interpretation of departmental statistics. In each Department of State there has been a large amount of unco-ordinated statistics related to very limited aspects of the department's work. By the extension of the survey method such obstacles can be overcome. Thus the data which it is most convenient for a department to obtain by a return can be supplemented in many ways by sample inquiries and thus assist in making decisions of policy. In this way a most flexible instrument for the compilation of a wide range of statistics can be developed. At the same time each department can remain in close touch with the collection of data, since the Survey normally discusses an inquiry in great detail with the officers concerned before it goes into the field. The experience of the Survey has shown during the past two years that its work has satisfied a real need for a specialist body able to advise on aspects of social inquiry which go beyond the official return, and there is little reason to suppose that this need will disappear when the War comes to an end.

Illuminating Engineering Society

THE annual report for the past year of the Illuminating Engineering Society, presented at the annual meeting held on May 9, directs attention to the formation of new centres in Bath and Bristol, and new groups in Derby, Huddersfield and Stockton-on-Tees. The Society is now organizing its activities through seven distinct areas, each with its own committee which in turn is represented on the areas joint committee. 243 new members have been added to the Society during the past year; the number of meetings held, upwards of sixty, exceeds that in pre-war days. Recent educational efforts include the organization of essay competitions for pupils in schools near Birmingham, and the giving of a series of Christmas lectures on "The Wonders of Lighting" to more than a thousand children in Bradford. The Society has been instrumental in forming a joint committee, with which leading physiologists are associated, to deal with the physiology of vision, and has completed, for the Ministry of War Transport, a special investigation into the brightness and legibility of traffic signs. Three of the series of illustrated lighting reconstruction pamphlets, dealing respectively with "Principles of Good Lighting", "The Lighting of Schools" and "The Lighting of Public Buildings" have recently been issued. The following officers have been elected for the present session: *President*, Mr. E. Stroud; *Hon. Treasurer*, Mr. N. V. Everton; *Hon. Secretary*, Mr. J. S. Dow.

Early Medical Books at Edinburgh

To illustrate a current series of lectures by Dr. Douglas Guthrie on "The Historical Background to Modern Medicine", there has been placed on view a collection of early printed medical books in the Upper Library Hall of the University of Edinburgh. Founded in 1580 as a "Town's Library" three years before the foundation of the University, or "Town's College", the University Library remained the only public library in Edinburgh until the establishment of the Advocates' Library a hundred years later. Naturally it contains many treasures, including a number of works of medical interest from which the present selection has been made. The most important and valuable items in the exhibition are Vesalius's "De Corporis Humani Fabrica" and Harvey's "De Motu Cordis". The beautifully bound copy of the former is the first edition, from the press of Oporinus of Basel, 1543. Beside it lies the fine two-volume edition, printed at Leyden in 1725 by Boerhaave and Albinus. The first edition of Harvey's account of the circulation of the blood is now an extremely rare little book, dated from Frankfurt, 1628. Visitors to the exhibition will have the opportunity of seeing two perfect copies, one of which belonged to Alexander Monro, the third of the dynasty of professors

of anatomy of that name. The first Alexander Monro, when appointed to the chair in 1720, kept a list of his students which is now shown, as also is a printed copy of the first thesis to be presented for the degree of M.D., Edinburgh. It is entitled "De Dolore", by John Monteith, and the date is 1726. Later works on view are the second edition (1800) of Edward Jenner's "Inquiry into the causes and effects of variolae vaccinae", the first British edition of Beaumont's "Experiments and Observations on the gastric juice, etc." (1838), Morton's "Remarks on the mode of administering ether" (1847), and J. Y. Simpson's "Account of a new anaesthetic agent" (chloroform) (1847). Another landmark of medical literature is Lister's "Introductory Lecture", delivered in 1869 when he succeeded James Syme in the chair of clinical surgery at Edinburgh, and with it may be seen a manuscript set of notes of Lister's lectures, in the writing of one of his most distinguished students and successors, Prof. Caird. A feature of the exhibition, and the most spectacular item, is a fine collection of illustrated herbals, including a magnificent copy of "De Historia Stirpium", by Leonard Fuchs, dated 1542, with coloured wood-cuts, and a catalogue of the Physic Garden of Edinburgh (1683), by the first professor of botany, James Sutherland. The exhibition, which has been arranged through the kindness of Dr. L. W. Sharp and the Library Committee of the University, will remain open until June 3.

Rhinology and Folk-Lore

IN a recent paper (*J. Laryng. and Otol.*, **57**, 272; 1943) on this subject, Dr. J. D. Rolleston remarks that in contrast with the dearth of popular synonyms for the ear and larynx, the nose enjoys an abundance of such terms, which he suggests is mainly due to the prominent position which the nose occupies in the face. Another explanation of these numerous synonyms is the connexion of a large red nose with chronic alcoholism, though such a connexion has been greatly exaggerated. One of the earliest beliefs connected with the nose is that it is the portal of entry of the life or the soul, as is seen from the well-known passage in Genesis relating to Adam. On the other hand, according to Sir James Frazer, the nose has been regarded by several savage races as the path by which life leaves the body. A popular belief in a close relationship between the size of the nose and the sexual organs in both sexes dates back to ancient times, and seemed at first to be confirmed at the end of the last century by the work of Fliess and others, who under the title of 'reflex neurosis' recorded a number of cases of uterine disease which had been cured by treatment of abnormal conditions of the nose. It now appears that the supposed connexion between the two organs in both sexes has been greatly exaggerated.

The folk-lore connected with sneezing is extremely abundant and dates back to remote ages, as is exemplified by many passages in the Bible, Homer, the Greek anthology, Xenophon and Petronius Arbiter. In accordance with the general rule in medical folk-lore, preventive measures are remarkably scanty in the case of rhinology and are chiefly employed in the management of epistaxis; whereas therapeutic measures are extremely numerous and can be classified under the headings of remedies of human origin, animal remedies, plant remedies, mineral cures, hydrotherapy, charms, patron saints and miscellaneous cures.

William Bartram of Philadelphia: Naturalist and Traveller

THE son of John Bartram, botanist to His Majesty for the Floridas, William Bartram (1739–1823) shared his father's interest in Nature, and in 1773–74 carried out an extensive survey in Georgia and Florida. The results of his "Travels" he communicated in two manuscript volumes to his patron, Dr. John Fothergill, an Edinburgh medical graduate who had settled, and made a fortune, in London. After the death of Fothergill, the manuscripts came into the possession of Sir Joseph Banks, and they are now in the library of the British Museum (Natural History). Through the generosity of the American Philosophical Society and the John Bartram Association, this interesting record, thoroughly annotated by Francis Harper, has just been published (*Trans. Amer. Phil. Soc.*, N.S., **33**, 121; Nov. 1943). It gives a picture of the primeval wilderness of the south-east of North America, of the beauties of scenery and the wonders of plants and animals, of the Creek, Cherokee and Seminole Indians, until then largely unspoilt by the 'civilization' of white men. It is true that many of the wonders described by Bartram were regarded with scepticism in later years by those whose authority gave them some claim to pronounce judgment; but it is one of the gratifying features of the investigations of Mr. Harper, who followed the Bartram trails over some ten thousand miles, that the authorities have been confounded and Bartram's accuracy vindicated, even in the much-disputed matters of the painted vulture of Florida and the bellowings of the alligators of St. John's, Florida, so circumstantially figured in the traveller's drawing, reproduced as Plate xiv in this paper.

Railway Signalling on London Transport

ACCORDING to a paper read recently in London by R. Dell before the Institution of Electrical Engineers, the power-signalling installation on the railways of the London Passenger Transport Board now covers 160 miles of double track. There are 3,281 stop signals, 2,726 of which are fitted with train-stops. Track circuits number 4,347 and there are 1,326 pairs of points. Although automatic signals are used wherever possible, 112 signal cabins are in use at junctions or connexions in the track layout. The passenger-train car-miles run each year total approximately 159,150,000. Power signalling has been in use practically throughout the system since it was electrified. The electrification of the District Line and the installation of power signalling commenced in 1904 and was completed by the end of 1905. The London Electric Tube Lines were equipped with power signalling from the start—the Bakerloo and the Piccadilly Lines in 1906 and the Hampstead Line in 1907. The Central London Railway was converted to power signalling in 1913 and the City and South London Railway in 1919. Except for these last two installations, the whole of the signalling system was originally operated on D.C. and track circuits were of the D.C. type with polarized relays in order to avoid improper operation by stray current from the traction system.

In the original installation the signals were all electro-pneumatically operated, with a moving spectacle in front of a fixed light for the tunnels and with semaphore arms in the open. All signals for passenger movements were provided with automatic trainstops. Although they gave remarkably satis-

factory results, the D.C. track circuits were not entirely immune from interference by stray current from the traction system; as a result, practically the whole of these track circuits have been replaced by A.C. equipment. At the same time, many additional safeguards were added to the system. Alternating current is now employed throughout for all signalling circuits as well as for the track circuits themselves.

Recent Earthquakes

During the period February 4–April 5, fifteen strong earthquakes were registered by the seismographs at Kew Observatory. The greatest of these were on February 29 and March 9. The shock of February 29 began recording compressionally at 16h. 40m. 22s. G.M.T. from an epicentral distance of 8,900 km., and after a full suite of pulses beginning with *iP* attained a ground amplitude at Kew of 110 μ at 17h. 18m. 53s. G.M.T. On March 9 the shock began recording impulsively at 22h. 13m. 06s. G.M.T. and attained a maximum ground amplitude at Kew of 420 μ at 22h. 43m. 49s. G.M.T. At Toledo (Spain) during February, twenty-four earthquakes were registered by the instruments. The greatest of these was on February 1 at 03h. 28m. 26s. from an epicentral distance of 3,700 km. (Turkey). This shock attained a maximum ground amplitude of 1150 μ at Toledo at 03h. 40m. 44s. Many after-shocks of this earthquake were recorded at Toledo during the month. Earthquakes which registered both at Toledo and Kew occurred on February 1, 4, 5, 15, 20 and two on February 29, the last of these having been mentioned above.

The first shock on February 29 occurred at 3h. 42·0m. G.M.T. Its epicentre has been found by the United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, to have been near lat. 13·7° S., long. 70·6° W., which is in southern Peru. The depth of focus was probably slightly less than 200 km. It was recorded at Kew on the vertical component seismograph with *iP* (dilatation) at 03h. 54m. 33s. G.M.T. and attained a maximum ground amplitude of 22 μ at Kew at 04h. 34m. 38s. G.M.T. At Toledo it was recorded at 3h. 54m. 00s., and attained maximum ground amplitude of 80 μ. The earthquake was recorded at Boulder City, Buffalo, Burlington, Chicago, Fordham, Georgetown, Huancayo, Pasadena, Philadelphia, St. Louis, San Juan, Sitka, Spring Hill and Tucson on the seismographs.

The Night Sky in June

Full moon occurs on June 6d. 18h. 58m. U.T., and new moon on June 20d. 17h. 00m. The following conjunctions with the moon take place: June 19d. 13h., Mercury 3° N.; June 24d. 17h., Mars 1° S.; June 25d. 02h., Jupiter 1° S. On June 24d. 17h. 38·3m. Mars is occulted by the moon, reappearance taking place at 18h. 54·2m. (for the latitude of Greenwich). Occultation of 308 *B* Leon. occurs on June 26d. 22h. 27·7m. (*D*), but there are no other occultations of stars brighter than mag. 6 during the month. Mercury rises at 3h. 11m. at the beginning of June and at 3h. 38m. at the end of the month. Venus is in superior conjunction on June 27, but is too close to the sun throughout the month to be well observed. Mars, in the constellation of Cancer, sets at 23h. 46m. and 22h. 33m. at the beginning and end of the month respectively. Jupiter, in the constellation of Leo, sets at 0h. 15m. and 22h. 30m. at the beginning and end of June respectively. Saturn is drawing close to the sun and is becoming difficult to observe. It sets at 21h. 17m. at the beginning of June—a little more than an hour after sunset. Summer Solstice commences on June 21d. 13h.

Announcements

Dr. W. J. Hall has been appointed assistant director of the Imperial Institute of Entomology as from June 1. Dr. Hall was a senior entomologist in the Ministry of Agriculture, Cairo, during 1920–26, and afterwards entomologist and director of the Mazoë Citrus Experimental Station and superintendent of the British South Africa Company's Citrus Estate at Mazoë.

Mr. Henry Clay, economic adviser to the Bank of England since 1933, has been appointed warden of Nuffield College, Oxford, in succession to Mr. Harold Butler.

The Association of Scientific Workers has signed an agreement with the Engineering and Allied Employers National Federation, whereby the latter recognizes the Association as representing scientific and technical staff in the industry.

Two scholarships have been given to the Mining Department of the University of Leeds. The first, to be known as Dr. Walter Hargreaves Scholarship, has been founded with a fund of £1,250, collected by the shareholders of the Briggs Collieries, Ltd., as a testimonial to Dr. Walter Hargreaves on his retirement from the chairmanship of the Company. Dr. Hargreaves has been a member of the Mining Advisory Committee of the University for many years and its chairman for the last twenty years. The second has been founded by the Anglo-Saxon Petroleum Company, which has provided a scholarship of £60 a year, plus fees, tenable in the Mining Department.

The Progressive League has arranged a series of five lectures on "Psychology and Problems of Society", to be delivered on Wednesdays at 7.30 p.m. beginning on June 7, in the Conway Hall, Red Lion Square, London, W.C.1. The speakers and their subjects are: Prof. F. C. Flugel, "The Psychological Basis of Permanent Peace"; Dr. May Smith, "Some Psychological Problems of Industry"; Dr. E. Glover, "Reactionary Aspects of Present Day Psychology"; Barbara Low, "The Psychology of Propaganda"; Major Emanuel Miller, "Psychiatry in a Planned Society". Tickets are 5*s*. for the course, 1*s*. 6*d*. for single lectures, and can be obtained at the door or from the Secretary of the League, 20 Buckingham Street, London, W.C.2.

The British Council has been permitted to print a small edition of the *British Medical Bulletin* for sale in the United Kingdom. The primary purpose of the *Bulletin* is to interpret British medicine to the overseas reader who would not normally consult the medical journals published in Great Britain. It contains reviews, abstracts, book notes and a list of the contents of current British medical and cognate journals. Applications for annual subscriptions (21*s*.) or for single parts should be addressed to the *British Medical Bulletin*, 3 Hanover Street, London, W.1.

Erratum. In the communication entitled "Gamones from the Sperm of Sea Urchin and Salmon", Nature, March 4, 1944, on p. 286, col. 1, line 18, for "*p*H less than 4·0" read "*p*H greater than 4·0".

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Activity of the Phytase in Different Cereals and its Resistance to Dry Heat

WHEAT, oats, barley and rye all contain between 0·18 and 0·26 per cent of phytic acid phosphorus. Wheatmeals and flours also contain an active phytase, and considerable interaction between this enzyme and its substrate may accompany the preparation of wheat for the table[1,2].

It was observed by Mellanby[3] many years ago that oatmeal is more rachitogenic than wheatmeal, and, later, that hydrolysis with acid or germination and malting[4] can remove the anticalcifying properties of oatmeal. Recent work has helped to explain these last two pioneering observations, for it has tended to incriminate phytic acid as the rachitogenic agent in cereals. In trying to account for the difference between oats and wheat in terms of phytic acid, it was found that oatmeal as purchased has a negligible phytase activity. It is accordingly suggested that this lack of phytase may explain Mellanby's results[3]. It is certain that only the merest fraction of the phytic acid in oatmeal could have been destroyed in preparing his puppies' food, whereas much of the phytic acid in the wheatmeals might have gone over to inositol and inorganic phosphorus before the puppies ate it. The lack of phytase in oatmeal explains why little or no hydrolysis of the phytic acid in oatmeal takes place in the making of porridge, even if the meal is left to soak overnight and then brought slowly to the boil.

The lack of phytase in oatmeal as purchased was at first tentatively attributed to the kilning process to which 'green' oats are subjected before being milled. Samples of kilned oats and of the green oats from which they had been prepared were, however, obtained from four well-known Scottish firms. These were ground up and incubated with ten times their weight of water at 50° C. and pH 4·5 for varying lengths of time. Two observations were at once made. The first was that the phytase activity even of 'green' oats was never more than a fraction of that of either English or Manitoba wheat. This led to an examination of rye and barley, and the results of all these tests are given in Table 1. It will be seen that the rye phytase was the most active. The inclusion of rye such as this in a wheaten grist would, therefore, tend to increase the amount of phytic acid destroyed in baking the bread, and the destruction in a rye bread must sometimes be very high. Dr. Kent-Jones kindly baked some rye bread from sample 2 according to the German technique[5], and 48 per cent of the phytic acid in this whole rye flour was found to have been destroyed in spite of the short time allowed for the bread to 'rise'.

It might be supposed that the apparent lack of activity of oatmeal phytase is due to this cereal containing a different and perhaps more resistant phytic acid; but this is unlikely, for when oats and wheat were boiled with hydrochloric acid the rates of hydrolysis of the phytic acids of the two cereals were found to be exactly the same (Table 1). Nor can the slow rate of enzymic hydrolysis in oatmeal be attributed to its phytic acid being present in a particularly insoluble form for, although the various samples of oats contained 44–72 mgm. of calcium per 100 gm. as against 29–41 mgm. for the other cereals, at least 75 per cent of the phytic acid in the oats was present as the magnesium and potassium salts, both of which must have been in solution at pH 4·5.

TABLE 2 THE PHYTASE ACTIVITY OF BRAN (AS MEASURED BY THE DESTRUCTION OF PHYTIC ACID) AFTER THE BRAN HAD BEEN HEATED DRY AND IN WATER AT 90° C.

All samples were incubated for 50 min. at 50° C. and at pH 4·5. The bran originally contained 10·3 per cent of moisture and 0·92 per cent of phytic acid phosphorus.

Time of heating at 90° C. (hr.)	% Destruction of phytic acid during incubation	
	After dry heat	After wet heat
0	87	87
½	87	0
1	85	0
2	82	0
5	78	0

The second observation was that kilning, even at temperatures of 260–360° F. for two and a half hours, did not destroy *all* the phytase. It was thought possible that this might be due to the enzyme being resistant to heat once it was dry. This was subjected to test. Some wheat bran was dried over phosphorus pentoxide in a serum-drying plant and afterwards heated in the dry state at 90° C. for ½, 1, 2 and 5 hours. Other samples were dropped into water at 90° C. and maintained there for the same times. The activity of the phytase was then studied by measuring the rate of destruction of the phytic acid in the bran on incubating it at 50° and pH 4·5. The results are given in Table 2, and it will be seen that whereas, as expected, the enzyme was completely and instantaneously destroyed in water at 90° C., it suffered no measurable destruction in 30 minutes at this temperature when it was heated dry, and very little destruction even after five hours. Further observations are in progress on the resistance of other enzymes to dry heat.

Our thanks are due to the millers who supplied the oats, to Dr. Greaves for drying the bran, to Drs. Moran and Kent for grinding the cereal grains for us, and to Dr. Kent-Jones for baking the rye bread. One of us (E. M. W.) is in the whole-time service of the Medical Research Council.

Production of Gliotoxin by *Aspergillus fumigatus* mut. *helvola* Yuill

IN the Research Items in NATURE of April 29, an account is given of the production of antibiotics by *Aspergillus fumigatus*. To supplement this annotation we submit this short account of our own work with the mould *Aspergillus fumigatus* mut. *helvola* Yuill. An earlier publication[1] has described the isolation of helvolic acid from 2–3-week cultures of this mould grown at 25° C. on a medium containing mineral salts and 4 per cent of glucose.

Discrepancies between the antibacterial activity of the culture medium, particularly during the first few days of growth, and the yield of helvolic acid obtained, suggested the presence of a second antibacterial substance. It was found that whereas the antibacterial activity of a 20–22-day culture is scarcely diminished at all by maintaining it at *p*H 10 for 5 hours at 37° C., this treatment completely destroys the activity of 3–4-day cultures. Since helvolic acid itself is stable at *p*H 10 under these conditions, it is clear that in the early stages of growth a second antibiotic, sensitive to very dilute alkali, is produced.

Investigation showed that the activity of the medium reaches a maximum after 8–9 days, then drops somewhat to reach a minimum after 16–17 days, after which it again rises to reach a fairly constant value after 20–22 days. At this time the mould is usually harvested for the isolation of helvolic acid. To isolate the second antibiotic, 5–6 day cultures are brought to *p*H 10 and immediately extracted thrice with equal volumes of chloroform, the total volume of chloroform being equal to the volume of medium being extracted. The chloroform extract is distilled under reduced pressure and the solid residue crystallized several times from hot alcohol. This process yields long colourless needles of the second antibacterial substance, the weight obtained being, roughly, 30 mgm. per litre of culture medium.

For the isolation of helvolic acid in this laboratory a magnesia column is used[1] and this is eluted with hot water. Under these conditions, the alkali-sensitive material is destroyed. We have identified the second antibiotic as one already described, gliotoxin, first obtained[2] as a metabolic product of the mould *Gliocladium fimbriatum* Gilman and Abbott. Our identification is based primarily on the data of Johnson, Bruce and Dutcher[3], who have investigated the properties of gliotoxin in considerable detail.

Property	Gliotoxin	Data of Glister and Williams
Melting point*	221° C.	218–220° C.
Optical activity	$[\alpha]^{25}_{D} = -255° \pm 15°$ (0·1% in $CHCl_3$) $[\alpha]^{25}_{D} = -290° \pm 10°$ (0·08% in C_2H_5OH)	$[\alpha]^{20}_{D} = -254°$ (0·6% in $CHCl_3$)
% Carbon†	48·08	49·9
% Hydrogen	4·96	4·4
% Nitrogen	8·15	9·5
% Sulphur	19·29	19·3

* In common with other authors we find that this value is obtained only if heating is very rapid.
† Analyses by Weiler and Strauss. Material dried at 50° C. *in vacuo*.

The molecular weight determined by an X-ray method (D. Crowfoot and B. W. Rogers-Low) is 330 ± 8. Johnson *et al.*[3] give 314 as their best value. The absorption spectrum, examined by Dr. E. R. Holiday, is consistent with the findings of these workers[3] that gliotoxin is an indole derivative.

The antibacterial activity of our material has been determined by Dr. M. A. Jennings, of this Department. In serial dilution tests, in which one drop of a 16-hour bacterial culture, diluted 1 : 1,000, was added to 5 c.c. quantities of nutrient broth containing diminishing amounts of gliotoxin, the minimum concentrations required to inhibit growth completely were:

Staph. aureus ..	.. 1 : 360,000
S. Typhi ..	.. 1 : 45,000
Bact. coli ..	.. >1 : 45,000

The sensitivity depends very much on the size of inoculum; for example, when the inoculum of *Staph. aureus* was increased a thousandfold, the minimum growth-inhibiting concentration was increased eightfold.

In the original publication[1] on helvolic acid, reference was made to fumigacin, an antibacterial substance obtained by Waksman and his collaborators[4] from *Aspergillus fumigatus* (Strain W84). The data then published were sufficient to establish that fumigacin and helvolic acid were not the same. In particular, fumigacin contains 3·7 per cent nitrogen (helvolic acid contains no nitrogen), 62·7 per cent carbon (helvolic acid, 69·1 per cent) and melts at 185–87° C. (helvolic acid, 212° C.). During the course of the present work, however, it has been shown[5] that fumigacin is a mixture of helvolic acid and gliotoxin. In view of this it seems rational to replace the term fumigacin, relating to a mixture of antibiotics, by the separate names gliotoxin and helvolic acid, which refer to chemical individuals. In this laboratory we have been able to obtain gliotoxin from 5–7-day cultures of a strain of *Aspergillus fumigatus* Fres. (Lister No. 982) kindly supplied by Dr. W. H. Wilkins, Mycology Laboratory, University Department of Botany. The mould was grown at 25° C. on Czapek-Dox plus 2 per cent glucose.

Shortly before submitting this note for publication, it was reported that gliotoxin has been obtained from a Penicillium as yet unidentified[6].

One of us (T. I. W.) is indebted to the Nuffield Fluid Research Fund for a grant towards expenses.

X-Ray Crystallography of Gliotoxin

WE have examined a specimen of gliotoxin prepared by G. A. Glister and T. I. Williams, as above. The crystals are four- and six-sided monoclinic plates elongated along [010], and our evidence on their morphology and optic character agrees very well with the measurements of Dr. W. C. McCrone[1,2].

The crystals gave good X-ray photographs from which the following data were obtained: $a = 18{\cdot}74$ A., $b = 7{\cdot}59$ A., $c = 10{\cdot}36$ A., $\beta = 80°$, correct to about ± 1 per cent; space group $P2$. Density = 1·543 ± 0·01.

Since the space group requires at least two molecules in the unit cell, the crystallographic molecular

weight of gliotoxin plus solvent of crystallization is 678 ± 16, or some submultiple of this. Chemical evidence suggests that the true molecular weight is of the order of half this, while the solvent lost on drying the crystals appears to correspond to the presence of $\frac{1}{2}$ H_2O per chemical molecule of gliotoxin (loss on drying, found 2·14 per cent, calc. 2·68 per cent). The calculated weight of half the crystallographic asymmetric unit, 339 ± 8, agrees very well with the figure 335 required for the formula $C_{13}H_{14}O_4N_2S_2.\frac{1}{2}H_2O$.

Formation of Hydrogen Ions in High Concentration by Ordinary Baker's Yeast

IN a previous letter[1] it was pointed out that when glucose is fermented by yeast, the release of hydrogen ions into the external solution can be greatly increased when buffering is avoided and the external potassium chloride concentration is much raised.

Previous fermentation for two and a half hours with 0·6 per cent glucose also assists in the subsequent acid production. After such preparative fermentation in the experiments here considered, 1 part of the yeast is well washed in the standard potassium chloride solution, and then left suspended in 0·5 part, and at a given time 0·1 part of 30 per cent glucose is added, samples of the mixture being taken and centrifuged after definite time intervals. The accompanying table shows the effect of increasing the potassium content in the external fluid, the samples being taken 20 minutes from the beginning of fermentation.

Potassium in centrifuged fluid		pH of the centrifuged fluid	Increase of free H ion conc. (allowing for activity correction) (mM./litre)	Decrease of potassium conc. (mM./litre)
At zero time (mgm./100 c.c.)	After 20 min. (mgm./100 c.c.)			
17	9	2·62	3	2
80	39	2·18	8	10
147	88	2 00	11·5	15
330	234	1 77	20	25
1760	1650	1·78	21	28

It will be seen that a pH as low as 1·7–1·8 (determined by the glass electrode) is reached when the potassium outside the cells is about $N/10$ with little or no further increase in the hydrogen ion release on increasing the potassium. The rise in the free hydrogen ion concentration accounts directly for much the greater part (about 75–80 per cent) of the potassium absorption after 20 minutes (the period of maximum potassium absorption), the remainder being probably also due to an exchange with hydrogen ion, the latter being slightly buffered by substances released during fermentation. What is of special interest here is the direct exchange of potassium for hydrogen ions, the latter reaching surprising levels. It is noteworthy that throughout the period of observation (up to 60 minutes) no appreciable change in the chloride content of the external fluid takes place.

As previously indicated[1] the source of the hydrogen ions would appear to be pyruvic or phosphopyruvic acid, though phosphoglyceric acid probably contributes also a slight amount. The pK values of pyruvic and glyceric acids are 2·5 and 3·6.

Where exactly the pyruvic acid is formed is at present obscure, except that it is almost certainly not formed throughout the yeast cell, but in some small surface region. In the external fluid, though pyruvic acid follows the potassium absorption (in inverse relation), it is present in very small concentration, and if liberated as the free acid, it could account for only a quite negligible fraction of the hydrogen ion concentration. This also applies to the total keto acids outside the cells.

It may be pointed out that free hydrogen ion in concentration indicated by a pH of 1·78 (and occasionally somewhat lower), in the presence of about $N/2$ chloride ion, is equivalent to free hydrochloric acid of approximately $N/50$ strength.

Fluorescence Spectra of Naphthacene Molecules in Solid Solution of Anthracene with the Variation of Wave-lengths

IN the crystalline state, pure naphthacene scarcely fluoresces, but it fluoresces with characteristic yellow-green light when mixed with anthracene or chrysene. Anthracene containing traces of naphthacene is quite suitable for studying the fluorescence of the latter. By exciting such a crystal by light of various wave-lengths, we have obtained the following results. (1) The positions and the number of the fluorescence bands of naphthacene remain unchanged with the change of wave-length of the exciting radiation. (2) Naphthacene fluoresces so long as the exciting radiation is not of longer wave-length than the longest wave absorption band of naphthacene. Solid anthracene has an absorption band lying at wave-lengths shorter than 400 mμ and fluorescence bands at 403, 422, 438, 445 mμ. Solid naphthacene has absorption bands at 425, 453, 485 mμ. In solid solution of anthracene, there is a red shift of these bands, and in the above crystal we find the absorption bands of naphthacene at 435, 460, 491 mμ. The fluorescence bands of naphthacene are at 498, 533, 574 mμ. They are due to naphthacene, for pure anthracene has no fluorescence bands in this region.

In the crystal mentioned above, naphthacene molecules are found to fluoresce by any radiation equal to, or shorter than, the longest absorption band of naphthacene. Using radiations 460, 475, 490 mμ respectively, we find the naphthacene molecules to fluoresce.

Bowen[1] has suggested that in such a crystal the anthracene molecules absorb light energy, give it to naphthacene and thus it fluoresces. But radiations of wave-lengths 460, 475, 490 mμ cannot be absorbed by anthracene molecules, which do not fluoresce when excited by these radiations. If excited by radiation of wave-length shorter than the longest absorption band of anthracene, both the anthracene

and naphthacene molecules fluoresce. Our experimental results that light of wave-lengths 460, 475, 490 mμ, which cannot be absorbed by anthracene molecules, can produce enhanced fluorescence of naphthacene, is against Bowen's hypothesis.

S. C. Ganguly.

Indian Association for the
Cultivation of Science,
210 Bowbazar Street,
Calcutta.
March 21.

[1] Nature, **142**, 1081 (1938).

Mr. Ganguly's observations, which are in complete accord with those of several other workers on the subject[1], can scarcely be said to refute the idea of energy transfers in crystals. Solid naphthacene fluoresces with its characteristic band emission, though rather faintly; when dissolved in solid anthracene it also fluoresces, as Mr. Ganguly notes, if illuminated by light which is directly absorbed by naphthacene molecules (4350–4000 A.). The vital question in the matter of energy transfer is what happens when shorter-wave light is used. If the mercury line at 3650 A. is used for excitation, the green fluorescence of naphthacene is visible in solid solutions containing only one molecule of naphthacene in 10^5 molecules of anthracene; at 1 in 10^4 this green fluorescence is strong, and above about 5 in 10^4 the green is brilliant while the violet anthracene fluorescence has disappeared. At 3650 A. anthracene absorbs much more strongly than naphthacene; the extinction coefficients in liquid solution are 1600 and 400 respectively, so that unless the ratio of extinction coefficients changes by a factor of about 10^4 in passing from solution to solid, the light must be absorbed by the anthracene molecules.

This being so, an explanation must be found for the emission by the naphthacene and the quenching of the anthracene emission. One possibility is that the anthracene emits its fluorescence (4450–4030 A.) and that this is reabsorbed by the naphthacene, the bands of which are in this region. However, the *maximum* extinction coefficient of naphthacene in (liquid) solution is 12,000[2]; this possibility is likely to be effective therefore only at molar ratios of anthracene to naphthacene of $12{,}000/1{,}600 \simeq 10$ (again assuming that the solid absorption ratios are not greatly different from those of liquid solutions). Since the maxima of the naphthacene absorption bands do not overlie the maxima of the anthracene fluorescence bands, this ratio must be an over-estimate, probably by a factor of 10.

We are therefore forced to assume an 'exciton'[3] mechanism. The electronic energy in an excited anthracene molecule must be mobile and capable of moving from molecule to molecule in the crystal by resonance. In pure anthracene the career of the exciton is terminated by fluorescence at some point. When naphthacene is present in solid solution, the exciton is trapped owing to the lower energy level of the excited state of the molecule below that of anthracene; the excess energy is lost as heat, and the fluorescence afterwards emitted is that of the naphthacene. Liquid solutions (as in benzene) of anthracene containing minute amounts of naphthacene fluoresce like pure anthracene instead of the green of naphthacene, the 'handing on' process being inhibited by lack of molecular proximity and orientation. For this reason impurities in crystals in general often profoundly alter the fluorescence properties while exerting no such effect when the whole is dissolved up in a liquid.

Reaction Between Solids

In reactions between solids the transport of the reactants through the reaction-product is rate-determining if the formation of the new compound on the surface of the reactants proceeds fast enough. The rate is then closely connected with the mobility of the 'reacting constituents', that is, ions and electrons, in inorganic substances. The behaviour of the reaction product as a semi-conductor is indicative of this mobility.

Experimental verification of recent theories[1] on this subject has nearly all been confined to simple reactions between a metal and a metalloid, such as in the corrosion of metals, and has been mainly carried out at temperatures not much above room temperature.

We have investigated the formation of spinel, $MgAl_2O_4$, from magnesia and α-alumina above 1,000° C. This reaction is probably characteristic of others encountered in the refractory and ceramic industries, and also in the production of many metals from their oxides by reduction with aluminium. Unpublished investigations in this laboratory have shown that spinel is an intermediate compound formed during the production of magnesium vapour by reduction of magnesia by aluminium *in vacuo*.

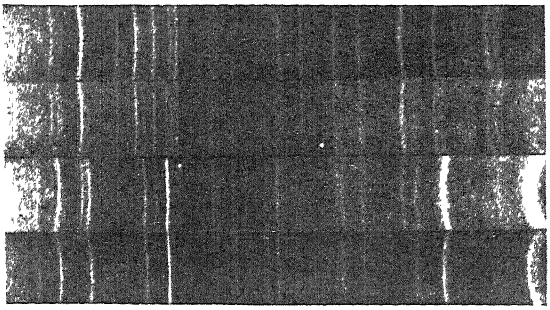
Alumina[2] and magnesia[3] are both 'reduction' semi-conductors[4], that is, substances the conductivity of which increases when heated in a reducing atmosphere (for example, hydrogen) or vacuum. By this treatment they lose oxygen and the excess metal is left behind as positive ions in interstitial positions, electrons being trapped in the ionic field[4]. Very probably the same applies to spinel[5].

If this is so, and if the reaction on the phase boundary proceeds fast enough, spinel should be formed at a higher rate in a reducing atmosphere or *in vacuo* than in air. To check this theory two sets, of four cylindrical briquettes, one inch in diameter and one inch high and each weighing 25 gm., were made up of powdered magnesia and α-alumina (passing 200 mesh, $r \leqq 0 \cdot 037$ mm.) in stoichiometric proportion. The briquetting pressure was 11·4 tons per sq. in. To one set there was added 5 per cent of metallic magnesium powder.

The briquettes containing the magnesium powder (set *a*) were heated to 1,000°, 1,050°, 1,100° and 1,150° C., respectively, in a high-frequency vacuum furnace evacuated to a pressure of 0·1 mm. of mercury and maintained at temperature for one hour. The briquettes of the other set (set *b*) were heated in the same furnace, and under exactly the same conditions of temperature and time as set *a*, but without evacuation of the furnace.

Debye diagrams (copper $K\alpha$) were then made from powder from each briquette and compared qualitatively with those of spinel and the original reaction mixture. In all the magnesium gettered specimens

Low orders High orders



(i) (ii) (iii) (iv)

X-ray powder spectra of the reaction $Al_2O_3 + MgO \rightarrow$ spinel.

	Per cent spinel.
(i) Alumina and magnesia	0
(ii) Alumina and magnesia, baked in air at 1,150° C.	20
(iii) Alumina and magnesia, baked in vacuum at 1,150° C.	65
(iv) Spinel	100

(set *a*), the spinel lines appeared stronger than in the corresponding air-baked ones (set *b*), this fact being perhaps most marked at a reaction temperature of 1,150° C. (see accompanying photograph). Photometer measurements on three lines of these specimens, using a 1 : 1 mixture of spinel and unreacted mixture as standard, showed about 65 per cent spinel in the (*a*) specimen and only about 20 per cent spinel in the air-baked one (*b*).

Using the relation between time and yield for powder reactions, these figures would indicate a more than ten-fold higher 'reaction constant' in the 'reduction' case. Neither the definition of the oxygen pressure and the powder size nor the accuracy of the analysis warrant more than the order of magnitude of this factor to be determined.

We wish to express our gratitude to Mr. W. E. Prytherch, director of research, High Duty Alloys, Ltd., for permission to carry out this work and to publish these results. Our thanks are also due to Prof. P. Gross, who instigated the work and whose advice was available at all times.

Age of the Saline Series in the Salt Range of the Punjab

IN his attempt to establish as Eocene the age of the salt of the Salt Range of the Punjab, Prof. B. Sahni[1] has succumbed to the temptation of generalizing too far from a particular instance. In 1925 I discovered fossil evidence indicating a Cambrian age for the Hormuz Series of the Persian Gulf, and in consequence I became an advocate for a similar age for the Saline Series of the Salt Range. Sahni now wishes to reverse this result and to make the Persian Salt Eocene—but the reaction is not reversible. The Persian salt domes occur in an area which is unquestionably autochthonous and, as they intrude rocks of Middle Cretaceous age in some cases, the salt must be of that age or older. Some of the associated rocks brought up by the salt are of a saline facies, with salt pseudomorph sandstones, gypsum, etc., and the fossil control establishes Cambrian, therefore the presumptive evidence is that the salt is also Cambrian. The map accompanying J. V. Harrison's[2] paper shows the breadth of the normally folded zone and the impossibility of assuming any large-scale thrust faulting. Also the Cambrian, where it appears in normal exposure farther to the north-west, has a similar salty facies.

I have not had personal experience of the Salt Range, but from a study of the literature and from conversations with Gee, Lehner and others, I find that the regional evidence is strongly in favour of a Cambrian age for the Salt Marl group. If Sahni's further work establishes beyond all doubt that the land-plant remains really belong to the salt instead of being caught up by it perhaps during the forward thrusting, then the answer may be that there are two salts, one of Cambrian and one of Eocene age. This would be quite an acceptable solution, and its only unpleasant consequence would be that it would bring to an end what has been a very stimulating controversy. In Persia there are thick deposits of Miocene salt, lagunar conditions locally in Oligocene, Eocene, Cretaceous, Jurassic and Triassic, and there is also Cambrian Salt.

There has been a tendency in the past on the part of many geologists to disbelieve in the possibility of salt masses being as old as Cambrian and still preserved, and Sahni is in good company in this respect. I answered similar criticism from Krejci-Graf[3] and Kossmat[4] in 1938[5]. In this connexion, attention might be directed to the extensive Middle Cambrian Salt deposits of Siberia, and also to lagunar developments in Upper Cambrian, Silurian and Devonian[6].

I hope to be able to send Sahni the samples from Persia for which he asks, and shall look forward to his further publication with great interest.

PROF. B. SAHNI[1] has anticipated me in publishing conclusive evidence regarding the non-Cambrian age of the Saline Series of the Punjab Salt Range.

In connexion with the researches at present being conducted in the Fuel Laboratories of the Imperial College, regarding the nature, composition and origin of kerogen rocks (oil shales and allied materials) of the world, I had the opportunity of examining in detail, during 1941–42, six specimens of kerogen rocks occurring in association with the Saline Series of the Punjab Salt Range and the salt

deposits of the Kohat region. The five specimens from the Salt Range were collected under the supervision of Mr. E. R. Gee, and the Kohat sample was collected by Dr. A. L. Coulson, both of the Geological Survey of India.

The position and occurrences of the six samples, according to the information supplied to Dr. G. W. Himus, Imperial College, by Mr. Gee and Dr. Coulson are as follows: Sample 1 (Warcha Mandi A): from the Lower Saline Series (in the gorge north of Fathepur Maira). Samples 2 and 3 (Warcha Mandi B1 and B2): from the Lower Saline Series (at the junction of Warcha and Jan Sak gorge). Sample 4 (Kalabagh): from the lower gypsum-dolomite stage of the Saline Series (in a tributary half a mile north-west of Kalabagh). Sample 5 (Makrach): bituminous shales, running among the dolomite and gypsum at the top of Saline Series (on the left side of Nawabi Kar, two and a half miles north-west of Makrach). Sample 6 (Kohat): 'oil shale' occurring in the gypsum capping the salt deposits near Kark.

Presumably the 'oil shales' mentioned by Prof. Sahni now being examined by him are similar to samples 1, 2 and 3.

Besides the two theories mentioned by Sahni, namely, (*a*) the Saline Series in the eastern part of the Salt Range is of Lower Cambrian or pre-Cambrian age, and (*b*) the Saline Series is of early Tertiary age, there is a third theory, (*c*), the Saline Series of the Salt Range is of Cambrian or pre-Cambrian age, but the salt deposits of the Kohat region are of Lower Tertiary age.

The question of the Kohat salt was decided by the discovery of fossil fish and Eocene foraminifera in the gypsum capping the rock salt. Thus the age of the Kohat kerogene shale is also Eocene. This means that there are not only two groups of salt deposits in the area, but also two groups of 'oil shales' of similar composition and nature, lying close to each other but of entirely different age. This conclusion on the very face of it appears improbable.

Sir Edwin Pascoe[2] in 1920 said: "That there should be two important salt-bearing groups, each containing hundreds of feet of salt, of entirely different age, the one Lower Cambrian or older and the other Eocene, occurring within 20 miles of each other (and indeed meeting each other near Kalabagh, A.L.), does not commend itself as probable". Fox[3] correlated the Kohat salt with the salt of the Salt Range on grounds of probability and attributed Cambrian age to both of them. Since then the age of the Kohat salt has been decided, but the salt of the Salt Range is still held to be Cambrian or older.

Not having sufficient field knowledge of the area, I raised the matter of the kerogen rocks with Mr. P. Evans of the Burmah Oil Co. (who also previously had produced evidences[4] of the Eocene age of the Saline Series) and in my communication to him I pointed out that the geochemical and petrological (especially the heavy mineral distribution characteristics) evidences indicate that the oil shales from the two areas are of the same age, suggesting Tertiary age of the Saline Series. Evans stated (March 19, 1943) that he thought the Kohat oil shale to be of Tertiary age, and Makrach and Warcha shales, on the grounds of Cambrian theory of the Saline Series, of Cambrian age; but he was not sure about the age of the Kalabagh samples. He thought it was surprising to find two series of oil shales of entirely different ages, occurring so close to each other, but perhaps not so surprising as the existence of two groups of deposits of the salt, and asked me to refer the question to Mr. Gee.

Further examination of the slides of the respective kerogen rocks decided the question. Down and Himus[5] have reported ill-preserved algæ and spores, and macerated plant debris from the Kohat shale. This was confirmed by me. Warcha and Kalabagh specimens, when examined under high magnification, revealed well-stratified and numerous minute fragments of blackened or carbonized and resinified angiospermous wood, fossil microspores and possibly some cuticles and pollen grains, occurring either in the shale matrix or in the dolomitic marl. The Makrach sample revealed numerous fossilized algal colonies, besides macerated plant remains. Owing to the ill-preserved nature of the specimens, it is difficult to determine the genus, but they resemble the algal bodies described from other kerogen rocks. The microstructures contain well-formed minute crystals of calcite, spherular pyrites and sometimes gypsum crystals formed in the cavities.

The identification of the 'yellow bodies' occurring in the kerogen rocks from various parts of the world as algal remains is now well established, since Blackburn and Temperly[6] convincingly proved that these algal remains do not differ in any material respect from the living alga *Botryococcus Braunii*. The nature of the algal remains in sapropelic deposits has been described by various workers, among them Zalessky[7] in Russia, Thiessen[8] and Bradley[9] in America, C. E. Bertrand and Renault[10] and Paul Bertrand[11] in France, and Edgeworth David[12] in Australia.

The nature of the calcite crystals and the pyrite granules is very characteristic in the fossil alga of all the kerogen rocks I have so far examined. This has also been noted by Bradley[9] and others[13].

Fox himself has pointed out that the occurrence of bitumen and oil in rocks of this area indicates Tertiary age of the deposits. Some have tried to ascribe the occurrence of bitumen and oil in the salt to migration of oil from upper horizons; for example, Nummulitic strata. Examination of the kerogen rocks from the Saline Series of the Salt Range and the Kohat area leaves no doubt that these are composed of the 'Ur-materials' of Pascoe, the mother rocks from which the lighter fractions of oil have migrated to other horizons.

Prof. Sahni is to be congratulated for deciding the second greatest controversy of Indian geology in the same manner as he decided the other great controversy, namely, the age of the Deccan Traps.

Composition of the Bracken Frond throughout its Growing Season

DURING 1942, the variation in the composition of the bracken frond throughout its growing season was investigated in Perthshire at Ballochraggan, the bracken experimental area of the West of Scotland Agricultural College. A uniform 100 yards square area of hill bracken was chosen on typical Scottish upland soil and from it fronds were taken at intervals throughout the season.

At each sampling a hundred fronds were weighed and the dry matter determined. It was noted that the percentage dry matter increased until the beginning of July and thereafter remained constant until September, when it again increased. It is interesting to note that the date on which the percentage dry matter became constant is approximately that regarded as most suitable for eradication by cutting.

The percentages of nitrogen, phosphorus, potassium, calcium and magnesium were determined in the dry matter and several points were observed.

The percentage of potassium (expressed as oxide) in the dry matter ranged from 5·60 in May to 0·86 in October, which emphasizes the recognized power of bracken to accumulate this element in the frond. It is debatable whether this high concentration is absolutely necessary for the normal metabolism of bracken, but if it is, then the problem of bracken eradication might be further explored by investigating the potassium absorption mechanism of the plant.

Throughout the season the percentages of nitrogen, phosphorus, potassium and magnesium in the dry matter progressively declined, the rate of fall being greater in the early stages. The percentage of potassium decreased considerably more rapidly than the others. On the other hand, the percentage calcium in the dry matter increased steadily until September, after which it decreased slightly, a condition often found in the leaves of plants.

The actual weights of certain elements in a hundred fronds were calculated for each sample, and it was noted that the maximum amounts of dry matter, nitrogen, phosphorus, potassium and magnesium occurred in the fronds about the beginning of August, whereas the maximum calcium did not occur until September. The amounts of dry matter, magnesium and calcium which were lost from the frond at the end of the season were relatively small, being 15·2 per cent of the dry matter, 24·0 per cent of the MgO and 11·9 per cent of the CaO. Conversely, the percentages of nitrogen, phosphorus and potassium lost were relatively great, being 72·8 per cent of the nitrogen, 77·8 per cent of the P_2O_5 and 63·2 per cent of the K_2O. The probable migration of nitrogen, phosphorus and potassium from, and the retention of the calcium and magnesium in, the ageing leaf are in accordance with the general views on such matters.

The rates of absorption are interesting. More than 70 per cent of the phosphorus was taken up before the second week of June, while less than 15 per cent of the calcium was absorbed in the same period. Between 30 and 50 per cent of the nitrogen, potassium and magnesium were absorbed during that time. Some authors have suggested that phosphorus is associated with intense meristematic activity, and the early absorption of P_2O_5 by bracken may be further evidence for this.

When the ratios of the amounts of certain elements absorbed by a hundred fronds at successive stages of growth were compared, it appeared that the only ratio which tended to be constant was the N/K_2O. This relationship has been observed in some other plants and suggests that nitrogen and potassium compounds may be closely associated in the metabolism of the frond.

It is intended to carry this investigation further in 1944 by examining and comparing the composition of rhizomes and fronds throughout the season. This should supply information about the movement of nutrients into the plant from the soil and their distribution between rhizome and frond. It is also hoped to study on similar lines the nutrition of poorly developed bracken and to correlate this with factors of the environment. At the same time the importance of information on the general biochemistry of bracken, about which surprisingly little is known, will be borne in mind.

The Ishihara Test for Colour Blindness

Vernon and Straker[1] claim that 5·37–9·45 per cent of colour blind men were found in Great Britain, according to district, averaging 7·49 per cent. This is about twice the accepted figure. They suggest the difference is due to use of "a modified form" of the Stilling and Ishihara Tests, which "picks out many of the colour-weak, or anomalous trichromats, as well as the strictly colour-blind".

In my investigation[2], 87 subjects tested with the Rayleigh equation were given the Ishihara Test (8th edition, 1939). They were 14 red-green blind men, 4 red-green blind women, 2 green anomalous men, 13 red-green weak men and 18 red-green weak women, 9 normal men and 27 normal women. The red-green weak have two to four times, and the colour blind five to twenty-one times the modal threshold for distinguishing the red-green variable disk from the standard yellow. The anomalous have a small threshold but a big deviation ($> 3\sigma$); the colour blind a very big threshold but usually a small deviation (whether protanopes or deuteranopes). The anomalous are not true intermediates between colour weak and colour blind[3]. Houstoun's[4] view is confirmed that the colour blind form a separate group in the population, because only 2 per cent of the men or women other than colour blind have more than three times, and only 2 of the 18 colour blind less than six times the modal red-green threshold, while true intermediates were not found.

The accompanying table shows that in the Ishihara Test no colour blind or anomalous subject in this experiment gave more than one reading unequivocally correct in twenty-four plates (the first of the twenty-five plates is always correct and only used to show the subject what to do). Four protanopes were not distinguished from deuteranopes by the test, nor two deuteranopes from protanopes. Moderately colour blind were not consistently distinguished from extreme, nor anomalous from colour blind, and this has been confirmed later with red anomalous, though some lesser deviants make fewer mistakes.

		Frequency of: Correct readings	Double readings	Errors
Extreme C.B	Prot. (3 ♂, 0 ♀)	1–2	0–1	23–24
	Deut. (3 ♂, 1 ♀)	1–2	0–2	22–24
Moderate C.B.	Prot. (3 ♂, 2 ♀)	1–2	1–5	18–22
	Deut. (5 ♂, 1 ♀)	1–2	3–6	17–21
Green anomalous. (2 ♂)		2	2–8	15–21
R-G- Weak (13 ♂, 18 ♀)	Mode	22	0	0
	Scatter	14–25	0–7	0–8
Normals (9 ♂, 27 ♀)	Mode	21	0	0
	Scatter	14–25	0–8	0–9

On a level of failure of nineteen or less correct in twenty-four plates, the Ishihara Test would have failed 9 of the 31 red-green weak subjects, but not consistently the weakest, and 9 of the 36 normals. Proportions of correct, alternative and 'blank' readings gave no accurate information about degree of weakness, though the test was used in a very strict manner.

Some red-green weak subjects might be dangerous and ought to be failed. The Ishihara Test is not capable of picking them out accurately. A warning to almost the same effect is given in the introduction to Stilling's Tables (17th edition, 1926).

The Ishihara Test is unsatisfactory as a scientific instrument[5]. It also errs on the side of severity, a good fault, but in an undiscriminating way, which is unfortunate, and Vernon and Straker's percentages may be unduly high.

Incidence of Colour-Vision Weakness

Vernon and Straker[1] reported that the incidence of colour-vision defect among recruits for the Royal Navy was least in the north-eastern part of Britain and greatest in the south-western part. They deduced that colour-vision defect may be racially connected with pigmentation.

The colour-vision of the first-year medical students at the University of Glasgow, who represent an educated cross-section of nearly all of the mixture of races in the west of Scotland, was examined with a set of Ishihara cards. Ten men were found colour-defective, out of 138 tested, an incidence of about 7 per cent. The colours of hair and eyes, and the general build, were noted. Five had hair of shades of brown; all five had blue or blue-grey eyes; one was very tall, three were stocky, and one was small and thin. One with black hair had brown eyes and was fairly tall; one with dark hair had hazel eyes and was small and thin. Three with fair hair had blue eyes and were of short stature.

The number is small, but the absence of any association of pigmentation or of physical type with colour-vision defect suggests that other possible causes of Vernon and Straker's interesting results should also be considered. For example, there may be some selection made by the men themselves, especially in the more educated groups, in which the individual who knows that his colour-vision is defective will tend to avoid presenting himself for the Royal Navy. Tests on army cadets at Glasgow have shown an incidence of colour-vision weakness higher than normal; this was found to be caused by the presence of several men who, but for their known colour-vision weakness, would have volunteered for the Royal Navy or the Royal Air Force.

The statistical surveys by Waaler[2] and von Planta[3] cannot be ignored. Waaler at Oslo examined 9,049 boys and 9,072 girls; von Planta at Basel examined 2,000 boys and 3,000 girls. The races are very different, yet the results are in agreement not merely in overall incidence but also in the incidence of each of the two defects, deuteranomaly (including deuteranopy) and protanomaly (including protanopy):

Incidence of colour-vision weakness.

	Males			Females		
	Deuter-anomaly	Prot-anomaly	Total	Deuter-anomaly	Prot-anomaly	Total
Waaler	6·10%	1·91%	8·01%	0·41%	0·03%	0·44%
v. Planta	5·75	2·20	7·95	0·33	0·10	0·43

These results indicate that the incidence of colour-vision weakness in Europe is probably independent of race, and that deuteranomaly and protanomaly are different colour-vision defects, inherited independently. That these two independent defects exist may be the reason[4] why the incidence of colour-vision weakness in females is 0·44 per cent, instead of 0·64 per cent as required by a simple theory of the inheritance of one sex-linked factor; the missing 0·20 per cent represents women of pseudonormal colour-vision, who have inherited both defects.

Road Safety and Road Structure

In his comments on my article "Road Safety and Road Structure" in Nature of May 20, p. 623, Lieut.-Colonel O'Gorman refers to the use I made of statistics in discussing the road accident problem.

Lest the reader is inclined to place undue emphasis on the secondary effects to which Colonel O'Gorman quite rightly refers, it should be pointed out that the sole purpose of the reference to statistics in the early part of the article was to support the conclusion that, "unless novel methods of prevention were introduced", there would probably be a serious increase in road accidents when traffic took to the highway again after the War.

As this is largely the foundation of Colonel O'Gorman's own praiseworthy efforts to get road accidents studied scientifically, I have felt it desirable to clarify the point.

W. W. Davies.

COLD DENSE MATTER

FOR his presidential address to the Section of Physics at the thirty-first Indian Science Congress, held at Delhi in January, Dr. D. S. Kothari took as his subject "Cold Dense Matter". Here the word 'cold' is used in a technical sense as meaning that any free electrons present constitute a degenerate gas—the actual temperatures can range from planetary temperatures to those of the interiors of white dwarf stars. Dr. Kothari's address has now been published, and it gives us a welcome summary of the main features of temperature- and pressure-ionization of matter at high and low temperatures and at high and low densities.

The thermodynamic theory of ionization in gases, though first used in particular applications by Lindemann (now Lord Cherwell), was given its dominating importance in astrophysics by the work of Saha. Saha showed that the dissociation of atoms into ions and electrons is encouraged by reduction of pressure or increase of temperature. But, as Kothari points out, pressure variations are comparatively unimportant in influencing the degree of ionization unless the temperature is of a certain order of magnitude given by the relevant ionization potential; for temperatures much lower or much higher, ionization will be either negligible or complete, whatever the pressure, and we therefore rightly describe Saha's ionization theory as the theory of temperature or *thermal* ionization. In his address, Kothari proceeds to discuss in some detail another kind of ionization, which he calls *pressure* ionization. This occurs in the case of relatively cold matter at high densities, when the atoms are pressed so tightly together that there is room neither for the outer electrons to be in bound orbits nor for them to be associated with particular ions. Kothari sums up the differences between thermal and pressure ionization in three compact propositions:

(i) Thermal ionization occurs in hot or non-degenerate matter; pressure ionization in cold or degenerate matter.

(ii) If, keeping temperature constant, the density be reduced, then the degree of ionization is increased for thermal ionization, and decreased for pressure ionization.

(iii) If, keeping density constant, the temperature be increased, the degree of ionization is increased in thermal ionization but remains practically unaffected in pressure ionization—unless the increase in temperature is so large that degeneracy is removed and pressure ionization passes into thermal ionization.

The discovery by Fermi and Dirac in 1926 of the correct form of quantum statistics to apply to gases had its repercussions on ionization theory: the early simple formulæ require modifications at large densities and low temperatures, where there sets in a 'degeneracy' which we have already mentioned. In addition, at very high temperatures further modifications are required, due to the need to use Einstein's modifications of Newtonian dynamics when the kinetic energy of thermal motion becomes comparable with the rest energy due to mass. The early part of Kothari's address contains a useful complete summary of the various discriminants which determine the different cases that arise at high or low densities or temperatures.

The later portions of his address are chiefly concerned with the applications of these general principles to the particular circumstances of the white dwarf stars and the planets. White dwarf stars were first recognized as configurations with degenerate cores by Sir Ralph Fowler. This theory has been considerably developed by Stoner and Chandrasekhar, and in his address Kothari rounds off these investigations, showing *inter alia* what had previously been assumed outright, namely, that for white dwarfs of mass exceeding a certain small critical mass, the stellar material is completely ionized. The application of the theory to bodies of planetary mass is a piece of original work of great beauty, due to Kothari himself. He shows that if we consider a series of 'cold' bodies of increasing mass, the radius increases to a maximum for a mass about one thousandth of that of the sun, and thereafter decreases; the physical reason is that ultimately increase of mass so increases the central pressure that the atoms suffer such a degree of pressure ionization that they finally occupy a smaller total volume in spite of the increased mass. The value of the radius at the maximum is shown by Kothari to depend to some extent on the chemical composition of the material, and he infers that the observed mass/radius values for Jupiter and Saturn are consistent with their being formed largely of (dense) hydrogen, whereas the terrestrial planets (Mercury to Mars) lie nearer the iron curve. The address concludes with a closely reasoned account of the probable evolutionary history of a body of planetary mass, together with Kothari's own difficulties with his theory.

E. A. MILNE.

MEDICAL EDUCATION IN INDIA

FOR his presidential address to the Section of Medical and Veterinary Sciences at the thirty-first Indian Science Congress held at Delhi in January, Dr. K. V. Krishnan chose "Medical Education" as his subject. Progressive medical educationists in India are not, he said, satisfied with the existing medical educational institutions, and wish to reorganize them in the light of recent trends of Western medical thought. It is now more than a hundred years since the first medical college was established in India and it is time for a stock-taking. India and the U.S.S.R. are the only two countries in the world which still have a dual standard of medical education, and both have decided to abolish it. The U.S.S.R. has already done much to abolish the lower standard. Madras and the United Provinces have already abolished it. Elsewhere in India there are still the medical schools which turn out licentiates with a lower standard of education and the colleges which produce university graduates. In the very near future, Dr. Krishnan hopes, there will be only the medical colleges.

Most of these colleges are not, however, planned according to the principles laid down by Flexner in his "The Idea of a Modern University". India is still producing the "tradesman doctor"; and should go on, as Britain, the United States and the U.S.S.R. have done, to the production of medical men whose ideals are the service of the public, the prevention of disease and the maintenance of health, rather than the cure of illness after it has been allowed to develop.

In the course of his address, Dr. Krishnan makes valuable suggestions for improvements along these lines. The libraries of the medical colleges should be extended and provided with foreign periodicals, text-books should be produced which deal with Indian

problems of health, men with the scientific bent of mind should be attracted to medicine and should be given better facilities for research. Clinical teaching should be improved by the provision of more beds per student and of teachers who emphasize the art of medicine and correct the tendency of students to depend too much on laboratory aids to diagnosis. More Indians should be given opportunities to become deans of medical colleges, and all teaching staff should be debarred from private practice. The teaching staff should, indeed, be specially chosen for the work and should find in it all the elements of an attractive profession. Improvement in the hygiene departments is also needed, and every medical college in a country where two-thirds of the deaths are due to bacteria should have a separate department of microbiology. Qualified men should all spend postgraduate time in hospital work and should also have the opportunity of doing postgraduate laboratory work. There should be adequate schemes for the training of specialists, refresher courses for general practitioners and others and courses in tropical medicine.

Discussing the supply of medical students, Dr. Krishnan finds that very few of them at present choose medicine as a profession for humanitarian reasons. India has not nearly enough medical practitioners. On the basis of 1 for every 1,000 people, which is the standard aimed at in Western countries, India should have at least 400,000, which is ten times the number that she actually has at the moment. It will be a long time before the number of colleges can be increased sufficiently to correct this deficit. Dr. Krishnan advocates instead a system of training medical students in batches or shifts—a system by means of which the U.S.S.R. is increasing the number of medical men without, he says, reducing the standard of education. The Leningrad medical school, he states, is said to train four batches of medical students at one time by a system of shifts "as in a factory", and he would like to see a serious trial of this mass-production of medical men in India. It is not easy to understand how such a system is compatible with Dr. Krishnan's other and excellent ideal of emphasizing the art of medicine.

Two outstanding needs of India are dealt with in some detail, the need for more women practitioners and the need for medical men in the rural areas. India has an even greater need for women than the U.S.S.R., where almost 50 per cent of the practitioners are women. But it is the need for rural medical men that Dr. Krishnan emphasizes. There are 388 million people in India and 95 per cent of them live in rural areas. "Intellectually, financially, physically and physiologically the villager may be said to be 'down and out'." In all rural areas are found the witch doctor, the quack, the *ayurvedic* and *unani* doctors and the allopaths. Everyone agrees that the witch doctor and the quack should be stamped out. Some think that the *ayurvedic* and *unani* systems should be retained, but Dr. Krishnan is among those who would abolish these also. India must make up her mind whether to abolish the allopaths as well. Most of her 42,000 existing qualified medical men are in the towns, which have enough doctors. For the rural areas the urgent need is a band of workers qualified in both medicine and public health, who have had also a training in rural problems and psychology. These men should be specially chosen for their desire to tackle the special job of attending to rural needs, to endure its almost continuous hardships and to go to the country people as friends and not as exploiters of their lot. They should be paid a fixed salary by the Government, with free quarters, and should agree to serve for ten years. Dr. Krishnan does not think there would be any difficulty in finding enough men of the right kind for this beneficent work.

Throughout his address, Dr. Krishnan refers to the interdependence of health control and social and economic problems, and thus alligns himself with progressive medical opinion everywhere. It is evident that, if he were an Indian medical student to-day, he would be found among the 5 per cent whom he mentions who chose the medical profession, not because it pays well, but because it offers a chance of serving their fellow men. His ideals are clearly those of the progressive social medicine advocated by Prof. J. Ryle (*Brit. Med. J.*, Nov. 20, 1943, p. 633) and other recent contributors to the *Lancet* and the *British Medical Journal*. These can perhaps be summed up in Ryle's statement that social medicine is "a logical development from and a direct expansion of clinical medicine, of medicine construed in its best Hippocratic sense and activated by the highest Hippocratic ideal; for 'where there is the love of man there also is the love of the Art' ".

Let us hope that the Government of India will, like the Government of Great Britain, take heed of the sufferings of the humble as well as of the great, and see that India gets the medical men and women whom she needs. If the princes and rajahs and merchants contribute to its finance, as Dr. Krishnan invites them to do, they will live in the future with Rockefeller, Nuffield and all the others whose gifts have led so swiftly and directly to incalculable relief of human suffering. G. Lapage.

THE BLACK REDSTART: A NEW BRITISH BREEDING BIRD

By R. S. R. FITTER
British Trust for Ornithology

Extraordinarily little is known of the process of extension and contraction of range which many animal species periodically undergo. Among British birds, the only two the extension of range of which during the past hundred years has been at all adequately described are the little owl (*Athene noctua vidalii*)[1], an introduced species, and the fulmar petrel (*Fulmarus g. glacialis*)[2].

An opportunity now presents itself to make a year-by-year study of a bird species, the black redstart (*Phœnicurus ochrurus gibraltariensis*), which is evidently at the beginning of the process of colonizing the British Isles, or at any rate their south-eastern corner. The black redstart was not known to breed anywhere in the British Isles before 1923, and has only quite recently begun to spread away from the southern coastline, where it secured its first foothold. In the summer of 1943, black redstarts were present in eleven English counties, five of which held at least ten breeding pairs[3]. It seems probable that but for the restrictions placed on observation by the War, many more breeding pairs would have been discovered.

The first breeding record for the black redstart in the British Isles was in Sussex, where a pair nested in maritime cliffs in 1923 and 1924, and probably

two pairs in 1925[4]. In 1932 a male bird was thought to be breeding in a maritime cliff in the south of England, possibly the same as the original locality[5]. The second locality where the black redstart has been proved to breed in England has only quite recently come to light. It is now known that three pairs of black redstarts nested in the Palace of Engineering at Wembley, Middlesex, in every year from 1926 until 1941, after which apparently increasing disturbance due to the War drove them away[6]. A fourth pair also nested in the same building in 1937. The next extension of range took place in the south-west, where the species has always been common as a winter visitor. Possibly from 1927, certainly from 1929, "a couple or so" of pairs of black redstarts nested annually on the cliffs of Cornwall[7,8]. The first wave of colonization was completed by pairs which nested in Kent in 1930[9] and in Woolwich Arsenal, London, in 1933[10].

The second wave of colonization, which has continued with gathering pace until the present, began with a pair that nested in Cambridge probably in 1936 and certainly from 1937 onwards[11]. In 1939 a pair bred in Ipswich, Suffolk, and birds were seen in the town in each subsequent year to 1942[12,13]. In 1940 occurred the first breeding record for Inner London, when a pair nested in the precincts of Westminster Abbey, and returned to breed in 1941[14]. This followed a period of increasing frequency of advance guards of non-breeding birds (cf. the fulmar[2]): two in 1927[15], two in 1936[16], one in 1938[17], two in 1939[18], six in 1940[19], and three in 1941[20]. At the same time, a tendency to spread into the suburbs also began: one was heard at the White City, Shepherd's Bush, in 1940[19], and in 1941 a pair nested at Wandsworth and males were seen at Hayes and Hillingdon, Middlesex[20]. In 1940 also nesting was first recorded in the Lower Medway valley, Kent, where it seems to have gone on ever since[21].

In 1942 the species seemed to take a big leap forward[22]. Breeding was proved in London (City, Notting Hill, Wandsworth), Cambridge, Whitstable, Kent, and Burlescombe, East Devon. Non-breeding birds were also present in London (more than twenty), Cambridge, Ely, Lowestoft (also in 1941), St. Leonards-on-Sea, Maidstone, Southampton, Plymouth (also in 1941), and even so far north as Sheffield. Altogether, forty-five to fifty non-breeding males were reported from various parts of England in addition to the six pairs proved to have bred. This compares with seven breeding pairs and nine non-breeding males in 1941. The advance of 1942 was maintained in 1943, when the species bred at St. Leonards-on-Sea, Hastings, Dover, the Medway valley, City of London (three pairs), Lowestoft, and Birmingham[3]. Non-breeding birds were present in Southampton, Dover, London, several Greater London suburbs, and Cambridge. The totals for 1943 were ten breeding pairs and twenty-six non-breeding males.

It is most desirable that every effort should be made to chronicle the further spread of the black redstart in 1944 and subsequent years. The British Trust for Ornithology has agreed to sponsor an inquiry, and all records for this and former years that have not been published should be sent to me at 39 South Grove House, Highgate, N.6. A point on which information is especially desired is the plumage of singing males, as it is known that in many cases these are immature and lacking the white wing-patch of the full adult plumage.

PETROLEUM REFINING AS A CHEMICAL INDUSTRY

IN an address delivered to a joint meeting of the Society of Chemical Industry (Manchester Section) and of the Institute of Petroleum (Northern Branch) on February 4, Dr. F. Kind outlined the way in which it has become possible for petroleum refiners to adjust production to market requirements, irrespective of raw material. The average crude oil contains 20–25 per cent of hydrocarbons suitable for motor spirit. Invention and development of the chemical cracking process has increased the potential yield to 50–70 per cent of the crude oil. In fact it has furnished a means of adjusting production of motor spirit and gas oil, kerosene and fuel oil from any given crude to meet demands. Similarly, development of the process of solvent extraction has made possible adjustment of chemical composition to market requirements.

Quite apart from being the most convenient source for production of all types of liquid fuel, lubricating oil and asphalt, crude oil is by far the largest and cheapest source of hydrocarbons accessible to man. Until recently, however, little use has been made of petroleum as a raw material for chemical purposes, the reason being that the chemical industry needs pure basic materials for syntheses and processes, and it is exceedingly difficult to obtain pure hydrocarbons from petroleum. With the development of cracking and reforming operations, however, a valuable source of pure hydrocarbons became available. The tail gas formed during these processes contains olefins in recoverable quantities, and it is possible to obtain comparatively large amounts of hydrocarbons with two to five carbon atoms, to separate *iso*paraffins from normal paraffins and olefins from paraffins. It is suggested that, using these individual hydrocarbons as raw material, it should be possible to build up higher hydrocarbons of known chemical constitution and in much purer form than that in which they could be obtained from crude oil. Further, it should be possible to build up hydrocarbons with certain desirable properties which are not present at

all in the original crude oil, or only in insignificant quantities. Already, vast quantities of hydrocarbons are being utilized in the production of synthesized aviation spirits and synthetic rubber. Other olefins, mainly ethylene, propylene and amylene, are being employed on a vast industrial scale, also to a lesser extent the paraffins. It may well be in the future that petroleum will be used more and more as a raw material for synthesizing special hydrocarbons, and that petroleum refining may turn more and more into a chemical industry.

In extension of a view held for many years that centres of consumption rather than oilfields are the right location for modern refineries, Dr. Kind advocates their development in Great Britain. They should be adapted to meet the special conditions prevailing and not necessarily modelled on American or Russian plants. Moreover, once established, the petroleum refining industry should refrain from entering the field of chemical industry proper. Two great industries are envisaged, one producing basic raw materials from petroleum, and the other manufacturing solvents, plastics, fibres, etc., from hydrocarbon 'bricks'. Establishment of these industries will not be an easy task, but there are, in Dr. Kind's opinion, few enterprises which offer such a rich reward for endeavour.

THE PERIDINIALES

DURING the cruise of the non-magnetic ship *Carnegie* of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington in 1928–29 intensive studies were carried out in the Pacific and North Atlantic Oceans, and, combined with the primary oceanographic investigations, a study was made of the plankton. The simultaneous collecting of samples and taking of hydrographic data afforded exceptional opportunities to study the relations between pelagic organisms and their environment. Among the organisms H. W. Graham selected for special study the difficult group of the Peridiniales, and from a preliminary survey it became evident that no general floristic study was possible in the light of the inadequate knowledge of the group. The peridinian life-histories are incompletely known, so that classification rests upon morphology of the cell, and especially upon the number and arrangement of the complex series of skeletal plates. On this basis, so far as it is known, Lindemann has described a number of genera, which have been utilized as a basis for the present study*. For description of the plate pattern, Kofoid's terminology has been used, though for the plate formulæ abbreviations of the plate names have been found simpler in practice than Kofoid's prime signs. The analysis involves special technique which lies mainly in fixation in formalin, separation of the thecal plates by hypochlorite treatment, and orientation and microdissection in glycerine jelly.

For intensive study representatives of five families of Peridiniales have been selected, with the following main objects in mind: to establish standards for analysis, to acquire a more detailed knowledge of the skeletal structure, to study the variation and to gain some concept of the inter-relationships of the genera and species. Besides the general plate features of the cell, Graham has found the number and arrangement of the plates of the ventral area particularly valuable for distinction of genera, and he illustrates the use of this area, the girdle and the hypotheca for this purpose. Owing to the preliminary establishment of genera on incomplete data as to cell construction, it is obvious that the genera and species of earlier classifications are bound to be considerably modified as study of the group proceeds.

The general discussion of the basis for classification and possible relationships of the genera is followed by a systematic description of the types analysed. The monogeneric family Ceratocoryaceæ receives full treatment, and the more difficult section, including Peridinium with its numerous species and variable forms, is studied with special reference to variability. The illustrations are very clear and well reproduced. There are also extensive tables of data bearing on distribution and environment.

Some of the forms, especially the relatively common *Ceratocorys horrida* and *Goniodoma polyedricum*, have proved valuable in tracing movements of oceanic water masses, as their distribution is closely correlated with temperature, so that records of negative occurrence are of significance.

SPECIFIC DIFFERENCES IN PETUNIA

THREE papers by K. Mather, A. J. Bateman and K. Mather, and P. M. J. Edwards, respectively (*J. Genetics*, 45, 215; 1944), deal with hybrids between *Petunia axillaris* and *P. violacea*. Important conclusions are made regarding the evolution of several characters.

In the first paper, K. Mather shows that *P. axillaris* is self-compatible and that *P. violacea* is a self-incompatible species. Hybridization of the two species shows that the factors $SaSa$ of *P. axillaris* do not inhibit the growth of pollen containing Sa, but the F_1 hybrids are of two types, self-incompatible S_1S_a and self-compatible S_2S_a. When such plants were crossed with *P. violacea*, seed was obtained, but the reciprocal cross was infertile. Similarly, the back-cross to *P. axillaris* gives different results in reciprocal crosses.

Mather suggests that modifying factors (polygenes) influence the expression of the main S allelomorphs. Within the species, the mechanism is stabilized and strengthened by selection of polygenes. When out-crosses are made, this polygenic background is altered. On this view the evolution of the incompatibility mechanism takes place slowly by the selection of those polygenes which favour the intensity of the mechanism.

A. J. Bateman provides further evidence that the S_1S_2 factors of *P. violacea* have a weaker effect in individuals with hybrid constitution. In the light of recent work on cytoplasmic influences, the discovery that pollen containing S_1 is mutually affected by previous association with Sa requires further investigation.

K. Mather and P. M. J. Edwards consider the inheritance of flower-colour in the above hybrids. They show that there are two main colour genes, Ww and Mm. *P. axillaris* contains $wwMM$ and *P. violacea* contains $WWmm$. The succeeding generations range greatly in colour, which is shown by the

authors to be due to the changed polygene complex; in one case a recessive and a heterozygote were the same white colour in the species hybrid. The authors discuss the effect of selection of polygenes upon inbreeding and outbreeding, genetic isolation and the evolution of species. They contend that the constant effect of natural selection of polygenes plays a large part in retaining the stability of the species and the vital constants of the species.

FORTHCOMING EVENTS

Tuesday, May 30

ROYAL PHOTOGRAPHIC SOCIETY (SCIENTIFIC AND TECHNICAL GROUP) (at 16 Princes Gate, South Kensington, London, S.W.7), at 6 p.m.—Mr. E. R. Davies will read a paper by Dr. L. A. Jones: "Psychophysics and Photography".

Wednesday, May 31

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London W.C.2), at 1.45 p.m.—Dr. R. W. Holland: "Education To-day and To-morrow", 10: Lecture summing up the Series.

Thursday, June 1

SOCIETY OF CHEMICAL INDUSTRY (AGRICULTURE GROUP) (at the Institution of Chemical Engineers, 56 Victoria Street, London, S.W.1), at 3 p.m.—Annual Meeting.

Friday, June 2

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5 p.m.—Sir Jack Drummond, F.R.S.: "The Hot Springs Conference and its Bearing on Nutrition in Great Britain".

GEOLOGISTS' ASSOCIATION (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. W. R. Jones: "Strategic Minerals".

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Capt. J. Morris: "Coupled Engine Torsional and Propeller Flexural Vibrations", followed by Informal Discussion on "Methods of Investigation of Engine Vibration".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

AREA REPRESENTATIVE (male or female) in each of the following centres: Birmingham, Cambridge, Cardiff, Exeter, Leeds, Leicester, London, Manchester, Newcastle and Reading—The Medical Adviser and Secretary, Central Council for Health Education, Tavistock House, Tavistock Square, London, W.C.1 (May 31).

ASSISTANT LECTURER AND DEMONSTRATOR (woman) IN CHEMISTRY—The Principal, Royal Holloway College, Englefield Green, Surrey (May 31).

PSYCHIATRIC SOCIAL WORKER—The School Medical Officer, Shire Hall, Nottingham (May 31).

HONOURS GRADUATE to teach MATHEMATICS and some PHYSICS, at the Burnley Municipal College—The Director of Education, Education Offices, Burnley (May 31).

GRADUATE MASTER FOR MATHEMATICS AND GENERAL SCIENCE—The Registrar, Loughborough College, Loughborough, Leics. (May 31).

LECTURER (man or woman) IN MATHEMATICS—The Principal and Clerk to the Governing Body, Wigan and District Mining and Technical College, Wigan (June 1).

SPEECH THERAPIST (temporary)—The Director of Education, Education Offices, 32 Dovecote Street, Stockton-on-Tees (June 2).

ASSISTANT MASTER to teach SCIENCE and MATHEMATICS for the Textile Industry in the Junior Technical School of the Bolton Municipal Technical College—The Director of Education, Education Offices, Nelson Square, Bolton (June 3)

TEACHER (full-time) of Day and Evening Classes in MINING and MINE SURVEYING at the Whitwood Mining and Technical College, Castleford—The Director of Education, Education Offices, Castleford, Yorks. (June 3).

TEACHER (temporary, full-time) OF MATHEMATICS, and a TEACHER (temporary, full-time) OF MATHEMATICS AND MECHANICS—The Principal, Acton Technical College, High Street, Acton, London, W.3 (June 3).

ASSISTANT MASTER (with Graduate or equivalent professional qualifications) to teach MATHEMATICS AND GENERAL SCIENCE at the Scarborough Technical Institute—The Secretary, Education Offices, County Hall, Northallerton (June 3).

ASSISTANT LABORATORY TECHNICIANS trained in histological and hæmatological techniques—The Professor of Pathology, Royal Victoria Infirmary, Newcastle-upon-Tyne (June 5).

HEAD OF THE BUILDING DEPARTMENT, and a TEACHER OF MATHEMATICS (temporary)—The Principal, Technical College, Church Street, Barnsley (June 5).

GRADUATE ASSISTANT MASTER to teach MATHEMATICS AND SCIENCE, particularly CHEMISTRY—The Headmaster, Junior Technical School and Evening Institute, Eastbourne (June 5).

LECTURER (full-time) IN CHEMISTRY AND PHYSICS in the Liverpool Technical College—The Director of Education, 14 Sir Thomas Street, Liverpool (June 5).

LECTURER (man or woman) IN CHEMISTRY—The Principal, Kingston Technical College, Kingston, Surrey (June 5).

LECTURER (full-time) IN CHEMISTRY—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11 (June 5).

LECTURER (male or female) IN ENGLISH and GENERAL SUBJECTS in the R.A.E. Technical School—The Headmaster, R.A.E. Technical School, Farnborough, Hants. (June 6).

ASSISTANT LECTURER AND DEMONSTRATOR IN PHYSIOLOGY—The Secretary, King's College of Household and Social Science, c/o University College, Leicester (June 10).

STAFF LECTURER IN SCIENCE AND HYGIENE—The Principal, Northern Counties Training College of Cookery and Domestic Science, at Tower House, Tweedmouth, Berwick-upon-Tweed (June 10).

CHIEF AGRICULTURAL OFFICER—The Deputy Clerk of the County Council, Shirehall, Shrewsbury, Shropshire (endorsed 'Chief Agricultural Officer') (June 10).

RESEARCH ASSISTANT (temporary) in the FIELD BOTANY DIVISION of the Ministry of Agriculture of Northern Ireland—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.2474A) (June 10).

LECTURER (temporary, full-time) IN PHYSICS—The Director of Education, The Polytechnic, 309 Regent Street, London, W.1 (June 12).

APPRENTICE SUPERVISOR by large Engineering works to supervise educational and training schemes for apprentices and young persons (Nottingham district)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2021XA) (June 14).

PROFESSOR OF BOTANY, ASSISTANT LECTURERS IN ECONOMIC HISTORY, GEOGRAPHY, BOTANY and ZOOLOGY, ORGANIZING TUTOR IN ADULT EDUCATION for Derbyshire, and a TUTOR IN PSYCHOLOGY—The Registrar, University College, Nottingham (June 14).

HENRY MECHAN CHAIR OF PUBLIC HEALTH—The Acting Secretary of University Court, The University, Glasgow (June 15).

LECTURER IN DIETETICS in connexion with Course leading to University of London Academic Post-Graduate Diploma in Dietetics—The Secretary, King's College of Household and Social Science, c/o University College, Leicester (June 17).

METALLURGIST by Firm of Engineers with wide interests (Ph.D., or equivalent, minimum technical qualification)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.2286XA) (June 17).

JOHN RANKIN CHAIR OF GEOGRAPHY—The Registrar, The University, Liverpool (July 31).

W. H. COLLINS PROFESSORSHIP OF HUMAN AND COMPARATIVE PATHOLOGY—The Secretary, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2 (July 31).

SENIOR LECTURESHIP IN THE DEPARTMENT OF METALLURGY of the University of the Witwatersrand—Dr. W. Cullen, 4 Broad Street Place, London, E.C.2 (July 31).

LECTURER (temporary) IN GEOGRAPHY—The Registrar, The University, Reading.

TWO MEN with experience in, or qualified for training in use of, Podbielniak and other apparatus for the fractional analysis of gases in the laboratory, for service with Petroleum Company in the Middle East—The Secretary, Overseas Manpower Committee, Ministry of Labour and National Service, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. 878/6).

DIRECTOR OF RESEARCH—The Secretary, British Iron and Steel Federation, Tothill Street, London, S.W.1 (endorsed 'Director of Research').

SECRETARY to the British Iron and Steel Research Association—The Secretary, British Iron and Steel Federation, Tothill Street, London, S.W.1 (endorsed 'Secretary').

ASSISTANT (male) IN BIOCHEMISTRY at the Courtauld Institute of Biochemistry—The Medical School Secretary, Middlesex Hospital, London, W.1.

GRADUATE ASSISTANT (temporary), with special qualifications in MECHANICAL ENGINEERING, a GRADUATE ASSISTANT (temporary) with First or Second Class Honours or Higher Degree in either MATHEMATICS or PHYSICS, and a well-qualified ASSISTANT (temporary) with trade experience for ENGINEERING WORKSHOP PRACTICE—The Principal, Mining and Technical Institute, Neath.

LECTURER IN MECHANICAL ENGINEERING—The Secretary, Woolwich Polytechnic, Woolwich, London, S.E.18.

RECRUITMENT AND TRAINING OF TEACHERS

TECHNICAL COLLEGES AND SCHOOLS

FOR many months past the pages of NATURE have referred to the great demands that will be made upon the industrial resources of Great Britain in post-war years and the consequent need for trained technicians and technologists to cope with the gigantic problems involved. Though the general character of the requirements of the situation have been surveyed by a variety of industrial, commercial, professional and educational bodies, it remains largely to the Board of Education to promote and later implement specific proposals for bringing about the necessary improvements in education and training schemes in order to relate them to the practical and social needs of the community in the best possible way. It is therefore gratifying to find that the recent McNair Report* not only gives a courageous and penetrating analysis of present deficiencies in the training of technical teachers (Part III, p. 108) but also advances bold suggestions for tackling what is stated to be "a comparatively new field of enquiry".

The keynote is struck when the report urges that "the standard of technical training which can be offered to those already in, or about to enter, industry, necessarily depends upon an adequate supply of teachers of high capacity and with personal experience of current practice. This fact is basic. Technical teachers, regarded collectively, constitute a key group in industrial development, yet their importance has hitherto been scarcely recognised even by those industries which most directly depend upon them for a supply of trained workers."

As in other fields of education, so in the technical field, greatly increased numbers of teachers will be required to implement the new Education Bill; indeed for the compulsory part-time requirements alone some 2,000–3,000 teachers of the ordinary technical and commercial subjects will be required. To these must be added "some thousands of additional teachers" for the older industries, for example, building, not to speak of the needs of the newer industries such as "plastics and large-scale catering" and many aspects of commerce, for example, marketing and export, which have as yet scarcely been considered. A further most urgent matter is the desirability of lightening the load of the present teachers so that they may be able to carry out research or make essential contacts with industry whereby their teaching may become vitalized and stimulating. These are only a few among the many factors which make it necessary to provide for large increases in the recruitment of technical teachers and render it important to frame schemes of training whereby the recruits may not only become efficient teachers but also be enabled to bring into the lecture room and laboratory a realism which unfortunately is frequently lacking to-day.

Witnesses from the chemical industry told the

*See also NATURE of May 20, p. 601, and May 27, p. 629.

Committee that many teachers of chemistry, in spite of their academic attainments, have insufficient knowledge of industry to adapt their methods to the needs of students; in courses for the building industry many of the higher teaching posts are held by architects who have had little or no experience of practical building and allied trades; textile industrialists often find that even graduates in technology are lacking in the groundwork of the fundamental sciences associated with their work. This latter criticism is also supported by the engineering world. "Commercial" teaching is often of a low order due to the use of antiquated systems and old-fashioned methods of instruction—a state of affairs which is inexcusable in view of the remarkable strides that have taken place in industrial administration in the last twenty years.

Worst of all, it is found that many technical teachers are ill-equipped to teach adolescents, and when it is remembered that, due to the association of junior technical schools with senior colleges, a given teacher under present conditions may have to teach boys of thirteen at one part of the day and lecture to honours degree students at another, it is seen that nothing short of a revolutionary treatment of the whole problem of the training of technical teachers will suffice.

The McNair Committee must be heartily congratulated for facing up honestly to these defects. It is true, of course, that some of the major deficiencies will disappear automatically upon the implementation of the Education Bill. Thus the junior technical school will be recognized for what it is, namely, an aspect of secondary education, and, as such, will come under secondary school regulations. The view that its past success is due to its pupils being taught by the same instructors as for senior students is, on examination, scarcely tenable. The McNair Report, therefore, in discussing the training of technical teachers, recognizes that "The establishment of compulsory part-time education with its vocational studies, and the provision of junior technical and commercial schools as a normal part of secondary education, will change the pattern of technical education and a much larger number of teachers of technical subjects will be required".

Little need be said about the recruitment of technical teachers in the past, for the majority seem to have drifted thither through the force of circumstances, there being no *ad hoc* recruiting ground or training available. Moreover, "the supply of technical subjects teachers ebbed and flowed with the prosperity or decline of industry. Teaching was to some extent a safe refuge from economic storms and, conversely, recruitment declined when teachers were most in demand". What about future recruitment? Clearly, this will depend on making the conditions attractive and laying down a definite policy for higher technical education. It is perhaps in reference to this that the McNair Report reaches the high-water mark of realism, for it bases its recommendations upon the closest collaboration between industry, commerce and technical education. A supply of good and appropriate buildings and equipment, salary scales and opportunities of promotion comparable with those of industry, possibilities of frequent interchange between teaching and industry, not neglecting opportunities for gaining overseas experience and ample facilities for carrying out research, are among the improvements in conditions that are envisaged. "But however many and varied the opportunities for interesting work and experience may be in theory, teachers will not in practice take advantage of them unless the root obstacle is removed. That obstacle is that many teachers in technical and commercial colleges, and especially the more responsible members of the staff, are heavily loaded with teaching duties. They have no time to spare. . . . Some local education authorities or governing bodies impose too narrow an interpretation of what constitutes a full-time appointment."

It must not be assumed that because there will be a great shortage of technical teachers therefore all comers must necessarily be welcomed, for it has to be recognized that teaching is an art and demands a certain aptness and attitude of mind, for even mediocre success. The "elusive qualities of personality" are difficult to describe and assess, but apart from these there are four other qualifications which ideally every teacher should possess, and to these must be added a fifth in the case of the technical teacher, namely, (1) a general education which fits him to be an acceptable teaching member of an educational institution, (2) a high standard of knowledge of his subject, or of skill in his craft, (3) the ability to teach, (4) an appreciation of the relation of his own subject to other realms of knowledge and of his educational institution to society at large and, especially, (5) an intimate acquaintance with his subject in its industrial or commercial setting, if possible through the practical experience of having played a significant part in industry or commerce. The report makes it clear that without a high standard of knowledge of his special subject or skill and an awareness of its industrial or commercial applications, a teacher has no proper place in a technical college. With this we must fully agree. Some good work as a teacher, however, might be done by one who was thus qualified but whose general education was somewhat shaky; this applies only to older persons who by virtue of wisdom and experience in other fields of human interest may be able to give useful teaching service, but for young teachers the full professional equipment is necessary. The point is, however, of importance in connexion with the emergency training schemes for dealing with the great demands for teachers in the immediate post-war years, and may conceivably be considered in connexion with the release of Service personnel, many of whom during the war period have had experience akin to that of teaching, for example, as responsible N.C.O.s or as service instructors.

The above emphasis on the importance of the possession of good technical qualifications does not imply that technical education is concerned wholly with imparting some 'skill', whether mental or practical; on the contrary, the training is only the medium through which a particular attitude to life and the world in general is developed, that is to say,

we must distinguish carefully between 'education' on one hand and 'training' on the other. It is true that the two cannot be entirely separated, but unfortunately it is possible so to stress the training that the educational process becomes of secondary importance, to the great disadvantage of the student. The report does well to emphasize this fundamental matter; indeed, the whole outlook of the report is refreshingly vitalized by its insistence on the *educational* functions of technical colleges. "The good technical teacher is no mere technician; he is also an interpreter of the modern world".

Quite the most inspired section on the training of technical teachers is that dealing with the part which industry must play. It is full of new ideas which, if carried out, will put technical education on a very high plane. Evidence shows that industry is ready and willing to play its part, and war-time contacts between colleges and industry have done not a little towards forging a close bond between the two. The nature of the bond is such that technical education and industry are co-equals. It is not therefore appropriate that the Board of Education should act as prime mover in securing co-operation but rather that the well-established and highly responsible professional institutions should take the initiative as intermediaries. These institutions already possess considerable experience of educational work and include among their members both teachers and acknowledged leaders of industry. They command the respect of all parties and between them cover a large part of the whole field divided up into its natural economic and technological units. Probably the formation of small standing advisory committees would be an effective means of keeping continuously in view the changing situation. The colleges themselves should be so closely linked with local industry that some of the teachers may even be associated with production in all its phases. Large firms might from time to time provide lecture courses and demonstrations in design and manufacturing processes. Experiments on these lines made to date have had remarkable success despite reluctance on the part of some industrialists to encourage the spread of their specialist knowledge. Furthermore, the release by industry of high-grade staff for part-time work in technical colleges would have advantages on both sides and would be of inestimable value to technical education, giving much-needed inspiration from the most powerful source from which the technical teacher can draw. What has been said about co-operation between the factories and the colleges applies equally to co-operation with research associations, which would confer great benefits upon technical teachers by holding refresher courses and visits to their laboratories for selected personnel.

A word must now be said regarding the arrangements for the actual training courses. "There is no generally accepted body of doctrine on the training of technical teachers, nor on the best methods of teaching some of the many subjects to the diverse types of students". The experience gained in Board of Education short courses has naturally been extremely suggestive, but there is still room for much further experiment. The report makes the valuable suggestion that "The time is now ripe for selected technical and commercial colleges and schools in association with teacher-training institutions to experiment . . . systematically and on a comprehensive scale". This training should, however, not be isolated from that of other teachers, and therefore should be undertaken by the area authority recommended elsewhere in the report, which should, for this purpose, include representatives of technical education in its constitution. The major part of the training should be carried out before the teacher begins to practise, for which purpose generous financial provision should be made, and in order to render the scheme flexible so as to deal with the vast range of interests involved, the course should be broken into units of comparatively short duration, for example, (1) education, (2) teaching, (3) study of the 'student', (4) industrial and commercial contacts. By conducting the course in conjunction with technical colleges, the services of experienced teachers would thus be effectively drawn upon and segregation of trainees would be avoided. "A liberal provision of refresher courses to make up for the comparativey short duration of the initial training period" would, of course, be necessary and would at the same time serve to correct any acquired errors of teaching technique and give encouragement to the young trainee.

It will be seen from the above that the McNair Report is a document of the greatest significance to technical education and one carefully calculated to remove the stigma resting upon it at present, namely, that "Technical education in this country has never received the attention it deserves and there has hitherto been no systematic provision for the recruitment or training of technical teachers".

In view of the key importance of technical education in our future national development, immediate steps should therefore be taken to provide the conditions for the implementation of the report at the earliest possible date.

HIGH POLYMERS

High Polymers

By Raymond M. Fuoss, J. Abere, W. O. Baker, Henry Eyring, John D. Ferry, Paul J. Flory, C. S. Fuller, G. Goldfinger, R. A. Harman, Maurice L. Huggins, H. M. Hulbert, H. Mark, H. Naidus, Charles C. Price, John Rehner, Jr., Robert Simha and A. V. Tobolsky. (*Annals of the New York Academy of Sciences*, Vol. 44, Article 4.) Pp. 263–444. (New York: New York Academy of Sciences, 1943.)

IN spite of the difficulty in prosecuting academic work on high polymers during the War, there has almost been a flood of literature, both books and discussions, on this topic. The reason is not far to seek. In the immediate pre-war years the subject was just getting into its stride, and though the rate of progress has naturally been drastically cut down, many workers have been able to make a substantial contribution when an opportunity for discussion has arisen. In the volume under review, the Physics and

Chemistry Sections of the New York Academy of Sciences combined to stage a joint discussion to bring both the chemical and physical aspects of the subject into contact and, it is hoped, alignment. There were eight papers contributed to the meeting, with a general introduction by R. M. Fuoss. Some of the material is new, but the majority of the papers are reviews of published work.

The subject may fairly be divided into two parts; the first dealing with the mechanism of the synthesis of macromolecules, and the second with structure and its connexion with physical properties. The question of reaction mechanism is now fairly well understood in its broad outlines, although there are many absolutely fundamental questions which have hitherto evaded solution. The two main processes of molecular growth comprise: (*a*) those in which each step in the addition of the monomeric unit is kinetically similar, although there may be small changes in the energy of activation and in the temperature-independent factor of the velocity coefficient as molecular size increases; (*b*) those formally similar to the classical chain reactions of kinetics. Generally, it would appear that stepwise growth is confined to poly-condensation reactions. In view of the apparent kinetic simplicity, it might be expected that the study of such reactions would give detailed information as to how velocity coefficients change with molecular size. The unfortunate trouble is that poly-condensations almost invariably occur in very concentrated solutions or between the two components alone, and therefore it is not easy to compute the magnitude of velocity coefficients. However, it is possible to measure the average energy of activation of the reaction and also to measure the distribution of molecular weights about the mean value. By postulating that the velocity coefficient does not depend on molecular size, it is rather interesting to note that the form of the distribution curves may be accounted for. The details of the various calculations are given in the review by Abere, Goldfinger, Mark and Naidus. What is not known with any great certainty is the extent to which the shape of the distribution curve is dependent on a variable velocity coefficient, for at present there is no reliable experimental information as to the nature of such a variation.

By far the greatest part of the experimental and theoretical work has been devoted to those reactions exhibiting chain-like characteristics. The classical chain theory has naturally been of immense value in quickly clearing away the preliminary difficulties, so that a real attack may be made on the problems peculiar to polymerization kinetics. Both the above-mentioned paper and another comprehensive review by Hulbert, Harman, Tabolsky and Eyring deal in some detail with the ideas now fairly well established in this part of the subject. They need not be referred to here. It is perhaps worth while, however, mentioning some of the difficulties. In those reactions where the time for the growth of the polymer is short compared with the half-life of the monomer, the expression for the velocity of reaction contains the three coefficients for starting propagation and termination of growth. The problem is to determine the numerical value of each coefficient. In general, however, we may only observe *two* significant things about the reaction; for example, the velocity and chain-length. One cannot, therefore, obtain the individual values of these coefficients and examine further how such coefficients vary with molecular length. Theoretically, it is possible to calculate the shape of the distribution curve according to various assumptions regarding the mechanism of these reactions and the variation of coefficients with size. The experimental difficulties in getting an accurate measure of the shape of the distribution curve rather restrict this method, so useful in principle, in providing a check on the mechanism inferred, not always unequivocally, from kinetic analysis.

While there is no doubt that in the polymers of vinyl derivatives the growing molecule is a free radical in some cases, as discussed in the article by C. C. Price, there is evidence that other types of active molecule exist. In the paper by Hulbert *et al.*, interesting speculations are made about the nature of the active molecule. With vinyl derivatives, however, it is not yet possible to draw up a summary showing how the velocity coefficient for polymer growth varies with the nature of the group attached to the vinyl group, and thereby probe deeper into the mechanism of polymerization.

The factors that govern the mechanical behaviour of high polymers are as yet only perceived with some difficulty, and no quantitative statements are possible. One method of tackling the problem is to take a given polymer and progressively modify the nature of the side-groups, simultaneously following the changes in physical properties. In this manner Baker and Fuller have prepared a series of polydecamethylene sebacamides using varying proportions of decamethylene diamine and 9-methyl nonamethylene diamine, and have examined the mechanical properties of stretched filaments, with simultaneous observations on structure by X-ray diffraction measurements. The straight-chain polyamide is rather brittle and easily crystallizes, whereas an increasing percentage of methyl groups destroys the regularity of the structure, diminishes the strength of hydrogen bonds and thus reduces lateral attraction between the chains. The 9-methyl polymer therefore exhibits rubber-like properties. Work of this kind serves to demonstrate forcibly that even relatively small changes in molecular architecture may lead to profound changes in mechanical properties. The accumulation of such systematic data will do more than anything else to help in establishing the general principles of a subject full of tremendous possibilities.

The statistical treatment of the theory of rubber elasticity resolved a problem which had seemed insoluble and provided additional support for the ideas concerning the structure of the rubber molecule. That theory initially assumed free rotation round carbon-carbon bonds. Evidence from other sources has accumulated to show that rotation is not free, though the potential barriers may often be as low as a few thousand calories. Florey and Rehner in their contribution to the discussion briefly examine the theory and conclude that the presence of low potential barriers does not lead to any important modification of the theory. They then report on some work from the same point of view on the vexed problem of the constitution of three-dimensional networks. Such polymers are by far the most difficult to investigate, for they cannot be got into solution; they merely swell to a gel, and X-ray methods, because of the impossibility of the existence of a high degree of order, do not yield a great deal of information. Florey and Rehner base their statistical theory on a three-dimensional model consisting of a tetrahedral unit in which four chains originate from the apices

of the tetrahedron and meet in a point—the point of cross-linking—each tetrahedron containing one cross-link. In this way they derive a relationship between Young's modulus and parameters signifying the number of cross-links present in the polymer.

Between the extremes of perfect elastic behaviour, rubber elasticity and the viscous behaviour of a Newtonian liquid, there is a region of behaviour in which a great many high-polymer systems lie. Much effort has gone to try to develop a convincing and all-embracing theory, but it is obvious that the description of the behaviour of a substance which may possess, according to conditions, elements of all three components, is a matter which may well defy solution. It is, however, necessary to systematize data so far as possible, since such polymers are used for a variety of purposes where deformation, especially under the prolonged application of a stress, is a matter of the first importance. Simha and Ferry deal with this aspect of the problem, the former considering particularly the flow of high polymers and the latter very concentrated solutions. There is also an article by Huggins dealing with the thermodynamic properties of high-polymer solutions.

There is, unfortunately, no account of the discussion of the papers presented at the meeting. This does not detract from the interest and usefulness of the volume, but the printed record of a discussion often serves to clarify obscure points and settle conflicting opinions on such a controversial subject.

PROBLEMS OF RACE

Race and Rumors of Race

Challenge to American Crisis. By Howard W. Odum. Pp. x+245. (Chapel Hill, N.C.: University of North Carolina Press; London: Oxford University Press, 1943.) 12*s*. net.

THE sins of the fathers are indeed being visited upon the children to the third, fourth and later generations in the southern States of the United States of America. Pressed by an uneasy conscience, the white South has tried here and there to reduce violence, to give somewhat better opportunities of education to the 'Negro', as he is called even if he often obviously has a good deal of white ancestry mixed in. But even those who want to treat the Negroes as brothers do not want them as brothers-in-law, and that is the root of the insoluble conflict. It is evident that recruitment and labour opportunities of the war-economy have given coloured folk a chance to escape from the old-time repression, and that it is becoming more and more difficult, in Africa as well as in the United States, to maintain a society in two layers without letting the lower one up anywhere. Both British and Americans are deeply concerned with the problems involved, and this book pictures for us what happens when the two layers talk about one another. The author gives a collection of fantastic rumours, many of which he helps us to see are quite baseless. But the rumour habit makes even the former limited inter-racial courtesies difficult to maintain; they are made to look like 'treason against your side', and this is inevitably the case, especially among the coloured folk.

The white South wants to be left alone, blames northern journalists, feels it must guard its traditions on behalf of its many brave sons fighting in far parts of the world, and, most of all, its girls whom those sons are likely to marry when they come back. But it cannot be left alone; coloured men in the armies of the United States will not come back to the old limitations. Inevitably the general level of education is still low among the children of the slaves, and the white South wants to protect its social standards and tradition of ease. But social standards are much more difficult to assess than are skin colour and hair type, and the protection of those standards is naturally enough made to include discrimination against, and segregation of, the coloured people. Several States have arrangements which in effect prevent Negroes from voting, and a number have laws making white-black marriages illegal; and Congress in 1944 is much concerned about some of these restrictions. Even were it possible to hand over a portion of the continent to the eleven million coloured people, that would not solve the problem as they would not have experience of either government or management.

The choice in these cases of bifid populations is ultimately between segregation and intermarriage, and segregation has hitherto meant anything but equality of opportunity for the coloured folk. They cannot be held down indefinitely, yet they have neither capital nor administrative experience. Meanwhile, the situation worsens and a world problem of racism on a larger scale than the Nazis talked about looms up, with only minor alleviations in sight.

H. J. FLEURE.

A MEMOIR ON SOME BOLETACEÆ

The Boletaceæ of North Carolina

By Prof. William Chambers Coker and Alma Holland Beers. Pp. viii+96+66 plates. (Chapel Hill, N.C.: University of North Caroline Press; London: Oxford University Press, 1943.) 43*s*. net.

MYCOLOGY is in debt to the University of North Carolina for the monographs which have been published by its press in the past, and now a new one is added to the series. Because of the great range of fungal species, we might expect that a book on the Boletaceæ of North Carolina would be of considerable value to students of these fungi in Britain. However, this purely systematic account will be of little real help to British workers, since of the seventy or so species considered less than a quarter would seem to occur in Britain.

The book is well produced and sixty-seven species of Boletus, four of Boletinus and one of Strobilomyces are considered, twenty-one species being illustrated in colour. There are also photographs of most of the species in fifty-five full-page plates at the end of the book. It is doubtful how much these photographs will help in identification, and they are certainly no substitute for good coloured reproductions.

There are four plates illustrating the spores of all the species considered. A glance at these suggests that only in a very few species does the spore size and form offer much help in making an identification. However, this is a step in the right direction, as progress in the study of the systematics of toadstools lies in paying more attention to microscopic characters. By such attention we may hope that the identification of toadstools will become more of an exact science and less a question of lore handed on by one generation of field mycologists to the next.

C. T. INGOLD.

Minerals in Industry

By W. R. Jones. (Pelican Books, A.123.) Pp. 149. (Harmondsworth and New York: Penguin Books, Ltd., 1944.) 9*d*. net.

THIS War, more than any other, has served, through the agency of the Press and the B.B.C., to bring home to the general public the importance to the belligerents of access to sources of minerals of all kinds. It is no doubt widely realized, too, that the question of mineral supplies will, or should, play an important part in international peace settlements, as well as in post-war trade.

"Minerals in Industry" provides in concise and very readable form all the information on the subject of economically important minerals likely to be required by general readers wishing to take an intelligent interest in such matters. The short introduction includes a brief account of the different modes of occurrence of ores and minerals. There follow, in alphabetical order, descriptions of a very wide variety of mineral substances and metallic ores, with notes on their uses in industry and the arts, together with particulars of the chief producing countries and world output. In a number of cases the average annual output from individual countries for the years immediately preceding the War is indicated diagrammatically; and there are outline world maps at the end of the book showing graphically the location of the sources of many of the more important minerals.

The inquiring reader can also glean from this little book why it is so important that a strict blockade of Germany, a country poor in mineral resources, should be maintained. He can further reconstruct for himself a picture of the disruption to the mineral supplies of Britain that resulted, not only from shipping shortage and submarine activities, but also through the spread of hostilities over Europe and into parts of Asia. How these difficulties have been met and overcome is a story that cannot be told until after the War.

Prof. Jones is to be congratulated on the addition of so excellent a book to the Pelican series.

V. A. EYLES.

The Aborigines—'so-called'—and their Future

By Prof. G. S. Ghurye. (Gokhale Institute of Politics and Economics, Publication No. 11.) Pp. xvi+232. (Poona: Gokhale Institute of Politics and Economics, 1943.) 8 rupees; 16*s*.

PROF. G. S. GHURYE, head of the Department of Sociology in the University of Bombay, here examines the position of primitive tribes in India and the question of their administration. He goes into their position with reference to their classification by the Census of India separately from Hindus and other religious divisions, and into the question of their relationship with Hindus proper; he examines their treatment by the Government of India, and by the British Parliament; he examines the reports, and recommendations, which anthropologists have made in regard to them; and finally he states the problem which, in his opinion, the present condition of the hill and forest tribes presents.

Prof. Ghurye is a whole-hearted supporter of the assimilation of the Backward Tracts to the rest of India politically, and has made the best case he could for this view; though he seems to realize the problem involved in protecting the aboriginal tribesman from the chicanery of Indian money-lenders and land-grabbers, and from the complete unsuitability of proceedings in Indian law courts. He has made himself very thoroughly acquainted with the literature on the subject, but his treatment of authorities does not appear to be entirely disingenuous. Thus he quotes Hutton's statement that the tribesman who claims to be treated as a caste in order to improve his social position frequently succeeds in achieving greater degradation. He goes on to add that Hutton does not attempt to explain why. If he had read to the end of the paragraph he quotes, he would have seen that the explanation given is clear enough; it is that the caste acquired is so often treated as an untouchable one, whereas, so long as the tribesman remains non-Hindu, he is treated with a certain amount of comparative respect. This is an aspect of the problem which Prof. Ghurye has not followed up, though elsewhere he remarks that the Satnami and Kabirpanthi sects are available "for any tribe to take recourse to avoid the stigma of untouchability". Unfortunately, the Chamars and others who belong to those sects are not the less untouchable on that account. Other points on which Prof. Ghurye fails to deal convincingly with his material are his specious argument that infant marriage is preferable to pre-marital license, and his attempt to show that the aboriginal tribes who are on the face of it doubtfully Hindu are quite as much Hindus as many of the lower castes. This may be more or less true in the case of some tribes and some castes, but most certainly does not hold good of all. Prof. Ghurye, wisely for the establishment of his case, avoids dealing specifically with the tribes of Assam, letting their case go with the rest by supposed analogy.

The volume would have been improved by the addition of a proper bibliography of the works quoted, an index, and at least one map.

Dictionary of Organic Compounds

The Constitution and Physical and Chemical Properties of the Principal Carbon Compounds and their Derivatives, together with the Relevant Literature References. Edited by Prof. I. M. Heilbron and H. M. Bunbury. Vol. 2: Eccaine—Myrtillin Chloride. Pp. viii+892. Vol. 3: Naphthacarbazole—Zygadenine. Pp. viii+978. (London: Eyre and Spottiswoode (Publishers), Ltd., 1943.) £6 6*s*. net each vol.

THESE two volumes complete the new edition. As indicated in a recent notice (NATURE, Nov 20, 1943, p. 586), they are reprints of the first edition with supplements containing data collected since the original publication of the work. The supplements comprise 42 pages in vol. 2 and 32 pages in vol. 3. The editors and publishers are to be congratulated on making available under very difficult conditions a new and complete issue of a substantial work of such value in organic chemistry and biochemistry. All practitioners of these rapidly expanding branches of science will hope that here is a dictionary which has come to stay and to keep in step with progress in these vast and complex fields of research. J. R.

The Microbe Man

A Life of Pasteur for Children. By Eleanor Doorly. (Puffin Story Books, P.S.8.) Pp. 112. (Harmondsworth and New York: Penguin Books, Ltd., 1943.) 9*d*. net.

THIS is a short and pleasant account of the highlights in the life of Louis Pasteur, written for children in simple language. The illustrations, woodcuts by Robert Gibbings, are handsome, but irrelevant.

DIAMONDS, NATURAL AND ARTIFICIAL*

By DR. KATHLEEN LONSDALE
Davy Faraday Laboratory, London

MANY people are interested in the diamond on account of its qualities as a jewel, its beauty and durability, or perhaps its value and portability. Others are chiefly concerned with its many industrial uses. To the geologist it is a fascinating mineral; the chemist regards it as the prototype of all the aliphatic compounds. But everyone must recognize it to be the aristocrat of the crystal world and must be interested to know why it attains such a high degree of perfection in so many of its properties. That question cannot yet be given a really adequate answer, for diamond still presents us with a very difficult problem. One point that needs to be emphasized is that each diamond is an individual; diamonds may look alike and yet behave very differently, with the result that it is dangerous, if not actively misleading, to generalize from observations, however accurate in themselves, which have been made on only one, or a few, specimens.

Consider the appearance of diamonds when illuminated by ultra-violet light. Some fluoresce brightly, others scarcely at all; with some the main fluorescence is blue, others are greenish, yellow, orange or pink. Crookes records that when diamonds are bombarded with cathode rays, they emit a light which may be bright-blue, pale-blue, apricot, red, orange, yellowish-green or pale-green. Such observations, even when made on many diamonds, although of considerable interest, are of little scientific value unless they can be correlated with other properties of the particular specimens observed. When placed in an X-ray beam, all the diamonds that I have observed fluoresced, if at all, with a greyish-blue colour, some more strongly than others. In most cases the luminescence ceased immediately the X-rays were cut off, but in others phosphorescence continued for several minutes and only died away gradually.

Or consider the colour of diamonds. Really clear-white diamonds are comparatively rare; most diamonds have a slight tinge of colour, and in many the colour is quite marked. But these colours are not necessarily stable; yellow diamonds are said to be comparatively difficult to change, but there are records of green stones which have become colourless, yellow or brown, when heated in an atmosphere of hydrogen; of black, brown and dark-green stones that have become violet. One colourless diamond heated in the absence of air became rose-coloured and retained this colour for several days in the dark, but the colour disappeared in sunlight, though it could be regained by reheating. On the other hand, a rose-coloured diamond became colourless when heated, but later regained its colour. Occasionally the colour is only skin-deep. Sometimes the colour changes are relatively uniform. Diamonds when strongly heated turn black, and when exposed to the α-rays of radium they turn green, but revert to their original colour on heating.

The density of diamond has been variously given as ranging from 3·01 to 3·56 gm./c.c., yet the distance apart of the carbon atoms of which the crystal is composed varies by not more than about 1 in 7,000 from one specimen to another. The true density, corresponding to the structure, is 3·515 gm./c.c. The observed variation on the light side may be due to gas or liquid inclusions, to the presence of light foreign atoms such as hydrogen or boron, or to the fact that the diamond investigated is not a single crystal. The forms of industrial diamond known as boart, carbonado or ballas tend to be light simply because they are variously arranged aggregates of very small diamond crystallites, and no aggregate of crystallites can ever occupy as little space as a single crystal of the same weight. Variations of density on the heavy side must be due to the presence of heavy impurity. F. G. Chesley (1942), using thirty-three diamonds from different localities, found by means of spectroscopic examination that aluminium, silicon, calcium and magnesium were present in all of them. He detected also the occasional presence of nine other heavy elements; but, apart from what may have been chance coincidences, he was unable to correlate his observations with the colour, habit or fluorescence of the specimens used. By the method he adopted, however, he could not have detected the presence of hydrogen, boron, nitrogen, oxygen, phosphorus, sulphur or the halogens, some of which are very probable impurities.

There are many important properties, however, which all diamonds possess in common. They are all composed mainly of carbon atoms, arranged to give cubic symmetry. The structure, determined in 1913 by W. H. and W. L. Bragg, consists of two interpenetrating face-centred cubic patterns, separated from each other by a translation of a quarter of the cube diagonal. The side of the unit cell is $3559 \cdot 65 \pm 0 \cdot 25$ X.U. (a real variation), giving a C—C separation of $1541 \cdot 37 \pm 0 \cdot 11$ X.U., or nearly 1·5445 A. It is interesting to note that each carbon atom in the structure is surrounded tetrahedrally by four others. It appears that in diamond the four valencies of carbon must be tetrahedrally directed, a beautiful confirmation of the theory of van t'Hoff, who postulated such a tetrahedral arrangement in order to explain the existence of *d*- and *l*-isomers of organic compounds containing an asymmetric carbon atom. This theory was also the foundation of Pasteur's work on the optical activity of the tartaric acids. We find that this tetrahedral arrangement of the carbon atom valencies is preserved, at least approximately, in all the aliphatic compounds, such as the sugars, paraffins and fatty acids.

One consequence of the tetrahedral arrangement of valency bonds is that diamond is not nearly so dense as it would be if the carbon atoms were close-packed. If atoms 1·54 A. in diameter were built up into a *simple* face-centred cubic pattern, the density of the resulting structure would be 7·653 gm./c.c. instead of 3·515. It is clear, therefore, that the hardness of diamond, its resistance to abrasion, which is one of its most remarkable and useful features, is not due to its compactness; for it would, in fact, be possible to pack more than twice as many atoms into the space actually occupied by the carbon atoms of diamond. It is rather due to the fact that each atom is sharing electrons with all its four neighbours in such a way as to build up a system of great engineering stability, which may be regarded either as one large molecule or as a series of interlocking long-chain molecules of immense length. Figs. 1 and 2 illustrate the types of chains that are associated with the projections along the cube axis and face diagonal respectively. Each atom is common to four chains of each type.

* Afternoon lecture at the Royal Institution delivered on March 30.

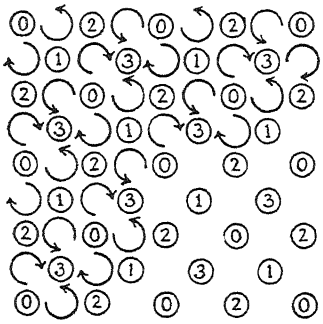

FIG. 1. INTERLOCKING SPIRALS SEEN IN PROJECTION ALONG CUBIC AXIS. 0, 1, 2, 3 ARE ON DIFFERENT LEVELS.

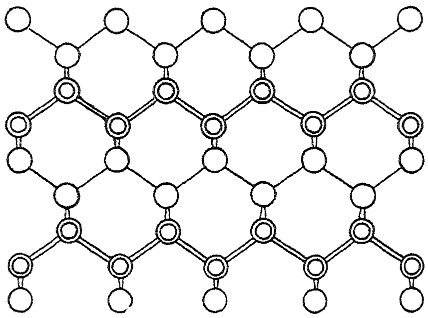

FIG. 2. INTERLOCKING ZIGZAG CHAINS (AS IN LONG-CHAIN PARAFFINS) AND CHAINS OF PUCKERED HEXAGONS (AS IN CONDENSED CYCLOHEXANE DERIVATIVES) SEEN IN PROJECTION ALONG A FACE DIAGONAL.

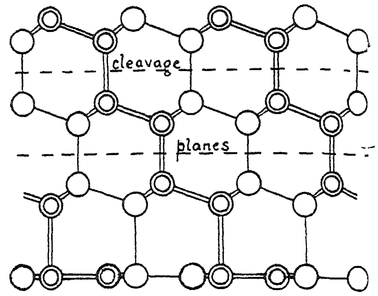

FIG 3. ARRANGEMENT OF CARBON ATOMS IN OCTAHEDRAL PLANES (111), AND FORMATION OF PSEUDO-GRAPHITIC LAYER AT SURFACE OF DIAMONDS.

○, ATOMS IN PLANE OF PROJECTION. ◎, ATOMS ABOVE AND BELOW PLANE OF PROJECTION.

We may expect that the presence of all these almost infinitely long chains will give diamond, *par excellence*, the properties that we have learned to associate with the *length* direction of long-chain molecules. It is always found, for example, that the highest refractive index γ in any organic crystal where the molecules are arranged in roughly parallel positions is associated with the longest dimension of the molecule, and that the longer the molecule, the higher the index. This property is used by crystallographers in order to help to determine the orientation of the molecules in unknown structures. We should expect, therefore, that the refractive index of diamond would be high ; it is, in fact, higher than that of any other known substance, and it is because of this quality and because of its high dispersive power that diamond, when cut as a gem, not only flashes brilliantly, but also flashes with all the colours of the rainbow.

There are not so many accurate data for the heat conductivity in various directions in single crystals, but there are enough to show that the conductivity is a maximum in the direction of the chain-length for crystals of any kind of electronic constitution, and that it is greater for perfect than for imperfect crystals. We are not surprised, therefore, to find that the thermal conductivity of diamond is high, as a simple experiment will prove ; it is higher than that of some metals and nearly 200 times that of glass. Dr. A. Müller has shown that the linear thermal expansion and compressibility of long-chain compounds are markedly less along the direction of their length than at right angles to that direction ; and we may expect, therefore, that for diamond the linear coefficient of thermal expansion will be small (it is one tenth that of glass and one twentieth that of silver), while the bulk modulus, or resistance to compression, will be large.

	Thermal conductivity	Linear coefficient of thermal expansion	Bulk modulus	Young's modulus
Diamond	0·35 at 18° C.	$0{\cdot}9 \times 10^{-6}$	$6{\cdot}0 \times 10^{12}$	$5\ 5 \times 10^{12}$ dynes/cm.²
Tungsten	0·35 ,,	4·3 ,,	3·04 ,,	3·91 ,, ,,
Steel	0·11 ,,	11·0 ,,	1·6 ,,	2·2 ,, ,,
Silver	1·00 ,,	18·8 ,	1·0 ,,	0·75 ,, ,,
Glass	0·002 ,,	9·0 ,,	0·5 ,,	0·7 ,, ,,

These properties are, of course, related to the toughness of diamond in wear, to the ability with which it will stand up to large pressures and to big and sudden changes of temperature, and therefore to its usefulness for industrial purposes. The forces of cohesion are not the same in all directions ; the very fact that diamonds usually grow as octahedra shows that, in the process of growth, atoms can be attached most easily in the direction of the cube axes and least readily along the body diagonals of the cube. Conversely, solution effects have shown very spectacularly that atoms are most easily detached along the cube directions, and in the same way diamond dies, after prolonged use, show signs of wear which is definitely a function of direction ; while it is a matter of common experience that diamonds cannot be polished along the 'grain' of their octahedral faces. The cleavage on the octahedral planes constitutes a point of weakness ; diamond dies often give way by fracture along a cleavage plane, and when diamonds 'burst' spontaneously, as they sometimes do*, it is also by octahedral rupture. Compared with that of many other crystals, however, the cleavage of diamond is difficult, because valency bonds have to be broken (Fig. 3) ; whereas in graphite, for example, the forces between successive atomic layers are so weak that slipping can easily occur. Hence the use of graphite as a lubricant. Diamonds, however, are also very slippery crystals to handle ; and it is possible that the electron orbits in the surface atoms may easily assume a pseudo-graphitic configuration, a hypothesis that would help to explain why diamonds can be electrified by rubbing.

Some properties of diamond, therefore, differ widely from one specimen to another, while other properties are shared in common by all. Let us now consider those respects in which diamonds seem to divide themselves into two types, well-defined although not altogether clear-cut. About ten years ago, Sir Robert Robertson and Drs. J. J. Fox and A. E. Martin found that whereas most diamonds showed an absorption band at 8 μ (1,288 cm.$^{-1}$), six out of three hundred specimens did not. In the ultra-violet region a similar difference existed ; the same six diamonds were transparent as far as 2250 λ, although most diamonds are opaque to radiation beyond 3000 λ. Later investigation on large numbers of diamonds from South Africa and India has shown that the 'transparent' diamonds are rare, but occasionally—such are the vagaries of the diamond—very small collections have proved to be all, or nearly all, of this rare type. Chesley found one 'transparent' diamond among those that he tested and it happened to be the purest of them all, but it would be most unwise to generalize from this one observation. The dangers of generalizing

* Two such specimens, lent by Prof. W. T. Gordon, were shown.

even from a number of observations are illustrated by the fact that Robertson and his colleagues found that most type I (opaque) diamonds were optically anisotropic, presumably owing to strain, but that the six type II (transparent) diamonds were nearly isotropic; Sir C. V. Raman, on the other hand, has found that type II diamonds sometimes show considerable restoration of light between crossed nicols, while many type I diamonds are isotropic. Most observers agree that type II diamonds tend to show a fine lamellar structure, and Prof. E. N. da C. Andrade and Dr. Martindale found that minute silver crystals would grow at random on the surface of a type I diamond, but along parallel (straight or curved) lines on a type II specimen. Scarcely sufficient crystals were examined, however, to be certain that this behaviour is characteristic.

About four years ago, Sir C. V. Raman directed attention to some anomalous spots and streaks associated with the X-ray reflexions from the octahedral planes of diamond, these being easily observable on Laue photographs taken in certain orientations. This phenomenon was investigated in great detail at the Davy Faraday Laboratory, and similar effects were found in association with other reflexions also, but no theory was found that would satisfactorily explain *all* the facts; nor is such a theory yet available. A suggestion by Sir Robert Robertson that it would be of interest to examine the Laue photographs given by both types of diamond was taken up, with most interesting results. It was found that whereas all type I diamonds gave the anomalous streaks with more or less intensity, type II diamonds showed no trace of them at all, nor of the other anomalous non-Laue effects observed in other orientations, although *all* diamonds gave extra spots due to thermal vibration of the atoms. The diamonds tested included several of those originally examined by Robertson *et al.*, as well as many others found to be either 'opaque' or 'transparent' in the ultraviolet. It was found, moreover, that type II diamonds were much better reflectors of X-rays than type I. A further difference was found in divergent-beam X-ray photographs, for type II diamonds always gave a clear, sharply contrasted pattern of absorption and reflexion lines, whereas the best type I diamonds gave a foggy picture on which few, if any, lines could be seen at all. These later observations definitely prove that type I diamonds are, generally speaking, 'perfect' in structure, but that type II diamonds are 'mosaic', that is, composed of small crystallites not quite regularly arranged. This fact, however, does not explain all the observed differences between the two types of diamond (which are tabulated below), although it does explain some of them. There is *no* difference in C—C spacing, Raman frequency, or specific heats at low temperatures.

DIFFERENCES BETWEEN TYPE I AND TYPE II DIAMONDS

Type I (relatively perfect)	Type II (mosaic)
(1) Common.	(1) Rare, in general.
(2) Infra-red: absorbs at 8 μ.	(2) Infra-red: transparent at 8 μ.
(3) Ultra-violet: absorbs beyond 3000 λ.	(3) Ultra-violet: transparent to 2250 λ.
(4) Often perfect octahedra, with perfect surface.	(4) Often lamellated.
(5) Give streaks and triangles on Laue photographs.	(5) No streaks or triangles on Laue photographs.
(6) Reflexions of moderate intensity.	(6) Reflexions very intense.
(7) Poor divergent-beam photographs.	(7) Excellent divergent-beam photographs.
(8) Slight photoconductivity.	(8) Marked photoconductivity.

A consideration of growth phenomena in crystals generally shows us that, in order to obtain 'perfect' crystals, slow and uniform variation of conditions is necessary; slow, regular evaporation or fall of temperature, for example. 'Mosaic' crystals are formed when growth is more rapid or irregular. Although the problem as to how diamonds were formed in Nature is still unsolved, it seems fairly certain that their growth was slow. Diamonds are mined from pipes of igneous origin, where they are found in the 'blue ground', kimberlite; but they almost certainly did not originate there. They are also found in alluvial deposits in river beds, and they have been thrown down from the skies in meteorites. Some of the earth-formed diamonds are not only huge (the Cullinan, which weighed nearly 1 lb. 6 oz., was obviously only part of a still larger diamond) but also practically perfect crystals, from which many superb gems can be cut. Scientific workers are not usually interested in crown jewels or even tiaras, but they would like to be able to make diamonds under controlled conditions. Rubies, sapphires, chrysoberyls, spinels and other gem materials can be made in the laboratory; why not diamond? The main answer is, of course, that in spite of its hardness and inactivity, diamond is not the most stable form of crystalline carbon, at least under ordinary temperatures and pressures. A great many attempts were made in the nineteenth century to find conditions under which carbon could be made to crystallize as diamond rather than as the more stable form, graphite. Moisson's well-known attempts to crystallize pure carbon from solution in iron or silver were believed by many, including Sir William Crookes, to have been successful, but none of his specimens remain. Sir Charles Parsons tried to melt carbon by the imposition of enormous instantaneous pressure and temperature, and also by means of hydraulic pressure and electrical heating; he tried to repeat and improve not only Moisson's method, but also the methods of all previous workers who had claimed any measure of success; and he tried other new methods; but towards the end of his life he and his assistant, Mr. Duncan, became convinced that neither they nor anyone else had ever succeeded in making diamond in the laboratory.

Meanwhile there were, in the possession of the Mineral Department of the British Museum, twelve minute crystals on a glass slide, labelled as being diamond, artificially prepared and presented by J. B. Hannay in 1880. These were presumably the remains of those tested and pronounced to be genuine diamond by Prof. Story-Maskelyne, the keeper of minerals at that time. Hannay's method was to take a mixture of 'paraffin spirit', bone oil and solid lithium, place it in a wrought iron tube which was then closed by welding, heat the tube in a reverberatory furnace for fourteen hours at a dull red heat and then, if it had not exploded, allow it to cool slowly. It was usually found that the iron had become porous on heating and had not held the pressure; but in three experiments out of eighty, the pressure *was* held in some way, for on opening the tube there was a rush of gas given off. A hard smooth mass which was found adhering to the inside of the upper end of the tube was crushed and some hard transparent crystals were found, some of which were tested by Hannay and some of which were sent to the British Museum for Prof. Story-Maskelyne to test. The report of Hannay's success was greeted by the scientific world of his day first with acclama-

tion, then with incredulity and finally with suspicion. It was thought that a practical joke may have been played upon him by an assistant, but according to Sir James French, who as a boy knew Hannay and who remembers the circumstances of the experiment, Hannay was well aware of this possibility and guarded against it. Hannay repeated the experiments a year later, using various tube linings; and he claimed success in four out of thirty-four experiments at this later stage. Other scientific workers accepted the experiment as genuine but believed that the crystals obtained were a carbon-rich form of carborundum, which is not unlike diamond in structure, appearance and properties. So late as 1902 Hannay indignantly refuted this suggestion, which had been made in the "Encyclopædia Britannica" of that date. An X-ray investigation of the twelve crystals preserved at the British Museum has proved definitely that eleven of them are diamonds; many of them show striations similar to those found on type II diamonds, and a special investigation of one specimen has proved that it is, in fact, a type II diamond. In spite of its minute size (less than 0·05 mgm. or 0·00025 carat) it is an excellent reflector, but it shows no signs of the type I streaks or triangles, although it shows the 'thermal spot' common to all diamonds. Although type II diamonds are comparatively rare in Nature, it is this mosaic type that one would expect to be formed under the relatively hurried conditions of a laboratory experiment. We can prove that the crystals are diamonds, but we cannot prove that Hannay made them. All things being considered, however, it seems only right to assume that he did; the matter was discussed at length in the correspondence columns of NATURE in 1943.

In some ways the problem of diamond is like a crossword puzzle. We have clues, but in some cases we do not know the solution; in other cases there seem to be more than one possible solution. But as Sir William Bragg said many years ago: "There is no cross-word puzzle that can compare in interest with the practical working out of a problem in Physics or Chemistry. You may say that to work at an amusing thing is not a very noble task. I can only answer that it makes a very happy life and I think that, if we can increase the number of human beings who find happiness in their work, we shall have gone some way towards creating a better state of things."

CHUNGKING INDUSTRIAL AND MINING EXHIBITION

By DR. JOSEPH NEEDHAM, F.R.S.
British Scientific Mission in China

DURING March an important Exhibition of Technology organized by the National Resources Commission (part of the Chinese Government's Ministry of Economic Affairs) was held in Chungking. This exhibition, which has attracted daily many thousands of visitors, deserves a world attention wider than the interest of the inhabitants of the Chinese capital, since it signalizes in a striking way the determination of China to embark upon large-scale industrialization, by which alone the standard of life of the masses in China can be permanently raised.

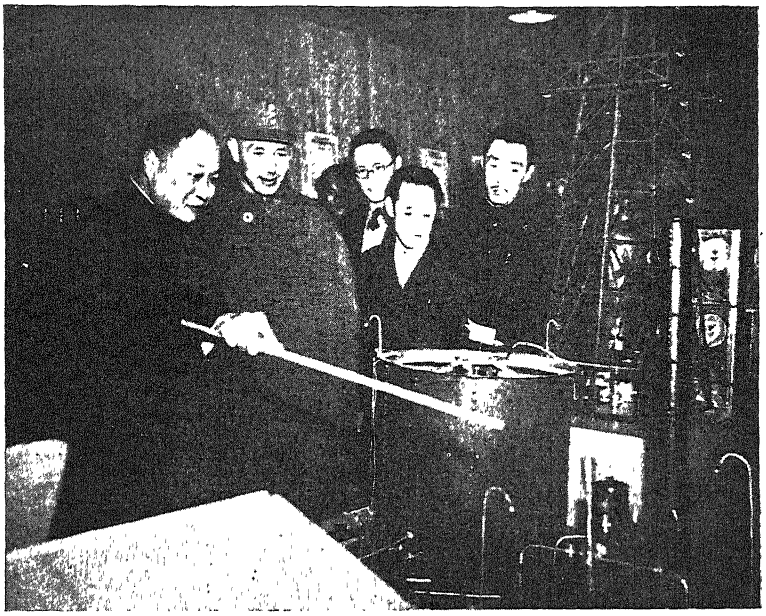
The exhibition occupied large and spacious hall, specially constructed for the occasion entirely of bamboo poles and matting, and set up on the campus of the Chiuching Middle School in pleasant surroundings. Facing the visitor in the imposing entrance-hall were the devices (acting as badges stimulating *esprit de corps*, as well as trade-marks) of the 105 mines and industrial plants operated by the National Resources Commission in Free China, that is, in the south-east, south-west and north-west parts of the country. The Commission employs some 170,000 workers, part of whom are skilled, and 12,000 staff, of whom some 42 per cent are trained engineers, chemists, etc., and 23 per cent in the administrative division. The walls of the entrance-hall were covered with maps and charts, and below were displayed a remarkable collection of mineral geological specimens, arranged with the aid of the Chinese Geological Survey. Here it may be observed that China produces 70 per cent of the world's antimony. Here one could handle a specimen of the ponderous tungsten ore, wolframite, of which China is the leading world producer. In the centre of the hall was an exhibit which should have been very educational for the Chinese public—a display of all the old provincial weights and measures side by side with the standard measures of weight and capacity. The importance of standardization was also shown by a medley of pieces of electric equipment, none of which will fit each other, presumably the result of pre-war purchases from Western countries, and showing the necessity of one standardized industry for all China. An idea of what standardization means was also given by a well-arranged exhibit of gun parts supplied by the arsenals of the Chinese Ordnance Administration.

Mining and Metallurgy

Proceeding along his fixed path, the visitor came next to the section on coal and oil. Here there were excellent stratigraphic mine models, pictures of types of transport, and a historical series showing the evolution of the miner's lamp in China from the Roman-style oil wick to the modern battery light. In the oilfield section, there was a magnificent model of the Kansu field in its desert mountains, and a number of working models not only of drilling derricks (about 6 ft. high) but also of the refinery. There were also actual specimens of the drilling bits and jigs, and a display of the various refinery products.

After this, the visitor reached the iron and steel section. There was a short historical exhibit going back to ancient Egyptian iron technology, and ending with modern metallographic pictures. The model blast furnaces were particularly fine, standing about 10 ft. from the ground and complete in every detail. One in particular was of interest as the original was largely built out of steel plate salvaged from river-steamers destroyed by bombing.

The metallurgical department continued into the non-ferrous metals section, which was particularly good. The display of specimens of economic minerals in the entrance hall, to which reference has already been made, was repeated on a smaller scale in each of the non-ferrous and mining halls; a very fine educational idea, since anyone who failed to take in the full import of the various minerals when he first saw them, could turn aside from the metallurgical models and familiarize himself with the ores on which the industries are based. Interesting copper-aluminium alloys with properties similar to nichrome steel were shown by the Electrochemical and Metallurgical



GENERALISSIMO CHIANG KAI-SHEK INSPECTING THE OIL-FIELD EXHIBIT. LEFT TO RIGHT: DR. SUN YU-CHI, GENERAL MANAGER OF THE KANSU PETROLEUM ADMINISTRATION; GENERALISSIMO CHIANG KAI-SHEK; DR. CHIEN CHANG-CHAO, VICE-CHAIRMAN OF THE NATIONAL RESOURCES COMMISSION; DR. WONG WEN-HAO, MINISTER OF ECONOMIC AFFAIRS AND CHAIRMAN OF THE NATIONAL RESOURCES COMMISSION.

Works at Sanchi under the direction of Dr. Yeh Chu-Pei (Yap Chu-Phay). This same works recovers zinc and copper from the bronze coins of former dynasties, of which a large stock has been collected, as well as smelting the native ores. It also produces copper of ordnance standard by electrolytic purification, of which an excellent working model was shown. Bauxite has now been discovered in Yunnan and Kweichow provinces, and an ingot of aluminium bears the triumphant inscription "The first Al sample industrially produced in China, at 4.30 p.m. on Dec. 11th, 1943". The sump mining of cassiterite tin ore was illustrated by an excellent timber model showing the washing troughs, and there was a working model of a tin smelting and purification plant. In the washing of wolframite ancient traditional wooden implements are used, also shown in model form. Particularly interesting is the technology of mercury. There were beautiful specimens of cinnabar, that precious substance of the early Chinese alchemists, and a series of models illustrated the different types of traditional smelting furnaces used in the different provinces. Finally, the antimony industry showed antimony ingots and models of paint-production plants.

Leaving the metallurgical section, one entered that of the refractories, where a large variety of heat-resistant bricks and acid-resistant stoneware was shown. There was a good display of China-made Seger cones.

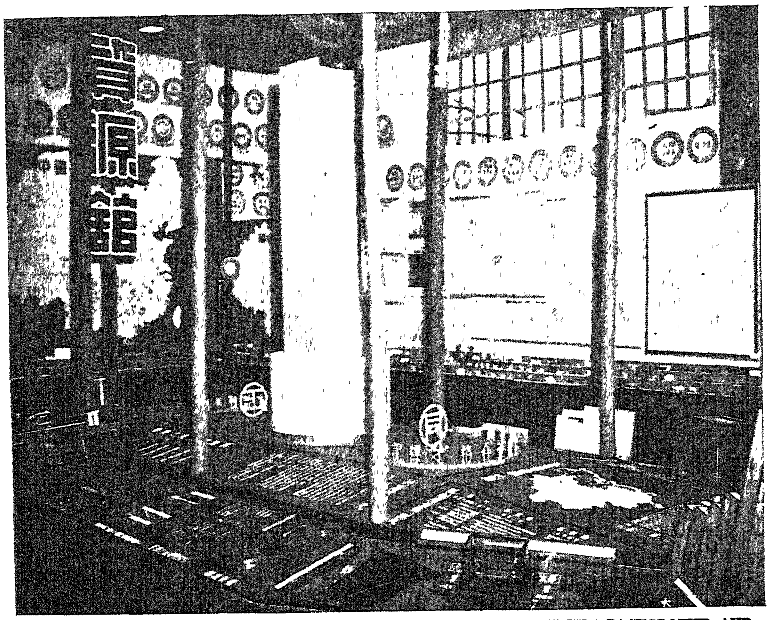
Chemical Industry

Next came the chemical industry. The production of power alcohol, so wisely encouraged as a contribution to blockaded China's supply of transportation fuel, was represented by a fine series of models, notably that from Dr. Chang Chi-Hsi's plant, and good exhibits, both on the chemical and the mycological sides. The production of petrol by cracking vegetable oils, the other main contribution to the fuel supply, was illustrated by a working model of a pipe-still, cracking chamber, and fractionating column, made entirely of glass, from the Tungli works (Dr. Hsu Ming-Tsai and Dr. Sun Tsun-Chueh). On an adjacent stand, surrounding a young tung oil tree, were shown all the products which may be (and, in most cases, are being) made from the oil, such as candles, margarine, vanishing cream, paint, varnishes, printing inks, solvents, lubricating oils, plastics, kerosene, petrol, Diesel oil, tar, and even oil-resistant synthetic rubber (through ethylene to thiokol). When tung oil petrol is no longer needed after the War, it should still be possible to base a great industry on the tung oil plantations.

Engineering

The electrical industry exhibits were arranged around a circular domed hall, indirectly lit, and with grass and herbs strewn on the ground. Music for the whole exhibition was provided by Chinese-made radio gramophones in the radio section. Among the great variety of apparatus shown in the hall one noticed aviation ground-station equipment transmitters of 20–100 m. frequency range (input 2 kW.: output ½ kW.); short-wave broadcasting transmitters for interprovincial communications (input 4 kW.: output 1 kW.); scrambler sets; radio beacon transmitters; military walkie-talkie sets with bamboo aerials; hand and 1-h.p. motor generators; 5-tube superhet receivers; 8- and 10-tube communications receivers (pronounced by an expert to be as good as any in the world); universal meters for currents and resistances; 50-watt public address system amplifiers; a very large assortment of radio valves; telephone exchanges with the receivers of lacquered wood owing to the plastics shortage; motors and switchgear; and intercommunication telephones. On an average, 88·3 per cent of the component parts of all this apparatus was made entirely in China; only in the case of some valves and meters are the Chinese still dependent on imports from abroad. They hope to raise the figure to 97 per cent this year. Besides all this apparatus, there was a wealth of wire and cables of all sizes, electric bulbs, dry cells and batteries, telegraph insulators and high-tension devices, silk- and rubber-covered flex, large accumulators made of wood and covered on the inside with an acid-resistant tung oil paint. One very educative exhibit was an illuminated circuit-diagram of a radio set actually working, and another was a flowsheet with all the component parts and their method of manufacture inserted. The biggest piece of Chinese-made apparatus in this section was a 1,200 kVA. step-up transformer for use in a phosphorus factory. Very good porcelain lamp sockets and switches of simple design replace plastic ones.

No less impressive than the preceding sections was that devoted to hydraulic power. The existing and planned power grids were shown on very clear maps, and there were a number of beautiful topographic running-water models which strikingly explain how various natural features in river flow can be made



ENTRANCE HALL, WITH GEOLOGICAL MAPS AND COLLECTIONS IN THE BACKGROUND AND THE STANDARDIZATION EXHIBIT IN THE FOREGROUND.

use of. Thus the Changshou plant has no dam, but a mill-race channel some 2 km. long, partly roofed as protection against land-slides, and leading to a penstock of 43 ft. fall. At Wanhsien, on the other hand, there is a low dam on top of a natural rock waterfall, and a rock-cut tunnel giving a fall of 45 ft. and an output of 300 kW. At Shanyuting the mill-race channel is carried over a side-stream by a viaduct before it reaches the penstocks, and gives rise to 1,500 kW. At Taohuachi the tunnel cuts across the short side of an isosceles triangle made by the river, short-circuiting several natural falls, and achieving a penstock fall of 270 ft. giving 900 kW. Some idea of the planned capacity of these west China networks may be gained from the following figures :

East Szechuan	647,000 kW.
West Szechuan	700,000
Kweiyang (Kweichow) ..	90,000
Kunming (Yunnan)	50,000
Djenbei	175,000
Hsiangchung	370,000
Ohsi	320,000
Hsibei (Kansu)	40,000

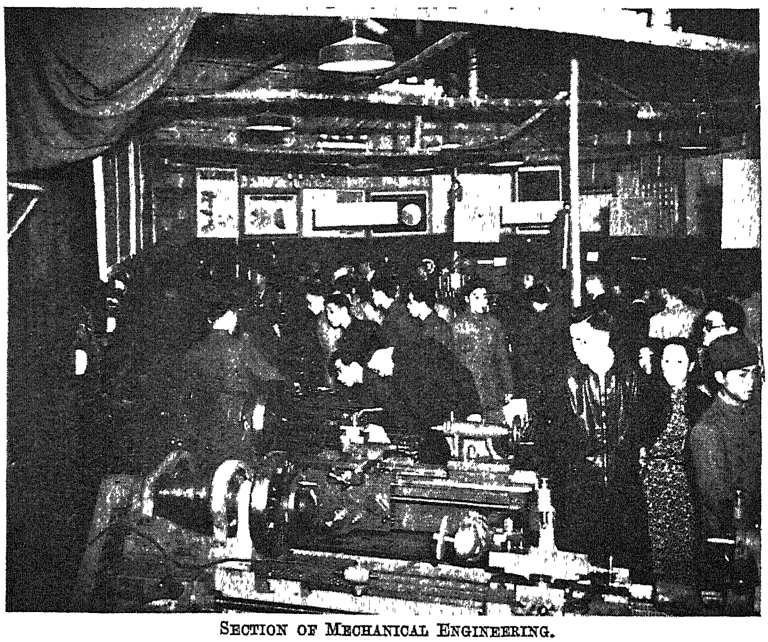
Not without interest, too, were the models of the high-tension line methods employed, the pylons being constructed mainly of wood.

The last section was that of mechanical engineering, showing the products of the different machine works. One saw first three models of power plants manufactured in China recently, namely, one 2,000 kW. boiler plant and two 150 h.p. water turbine and generator sets. On the other side were exhibited an actual six-cylinder stationary Diesel engine and generator set of 300 h.p. and one 10 h.p. gas engine set. Next in line came the various types of industrial machinery and motor-vehicle parts and also a set of village cotton-spinning machinery. The farthest corner contained the exhibit of precision tools and machine tools. The former included many items in common use such as lathe and drill chucks, gear cutters and hobs, micrometers and surface plates, while the latter included bench motor drills, drill presses, lathes, shapers and milling machines. Many of the items exhibited in this section were produced by China's biggest machine works, that at Kunming, directed by Dr. Wang Shou-Chin.

Throughout the exhibition the visitor noticed from time to time interesting photographs showing the welfare for the personnel (hospitals, schools, pithead baths, and the like) undertaken by the various plants. In this respect, the National Resources Commission stands as a striking example to private firms in Chinese mining and industry, where the workers' conditions are sometimes still in a distinctly backward state. Those who, like the present writer, have had the privilege of visiting many of the plants under the National Resources Commission, know that these pictures are no mere propaganda, but do actually represent the facts.

The Future

A Western man of science came away from the Exhibition with two main impressions. In the first place, from what has been said above, it is clear that under the vigorous direction of Dr. Wong Wên-Hao, Minister of Economic Affairs and chairman of the National Resources Commission, and Dr. Chien Chang-Chao, vice-chairman of the Commission, the Chinese people have now the embryo (and by no means at a very early stage) of a Science Museum on



SECTION OF MECHANICAL ENGINEERING.

the lines of South Kensington. It would be a disaster if all these models and collections, now so carefully assembled, were to be dispersed or lost, and all those interested in science and technology in other lands will agree with me in hoping that some arrangements will be made for preserving the present exhibition as a germ of a Chinese National Museum of Science and Technology. I am informed, indeed, that it is likely that some such arrangements, in conjunction with the Ministry of Education, will be made.

The second, and more far-reaching, point is, of course, that the Exhibition demonstrates, once and for all, that given the tools of the trade, Chinese technologists, engineers and scientific men are the equal of any in the world. To me, not unfamiliar with them beforehand, this came as no surprise, but it is a point which ought to be brought home to all those in Western countries who are concerned with post-war trade relations with China. Any idea that the Chinese are personally unfitted for technology and industry is a complete illusion. Any idea that they do not wish to industrialize their great country and will for ever be content to accept the industrial products of other countries is also a fatal mistake. They deserve, and should receive, every help in their industrialization. It was interesting to hear the comment of a Western diplomat who had spent many years in Japan, that in spite of the much-vaunted industrialization of that country, he had never seen there so well-arranged a technological exhibition.

At the present time, Chinese science and technology are encountering formidable obstacles. There is the state of blockade, which prevents the importation of essential apparatus if of any considerable weight; and there are the difficulties of transportation within the country, which lead to serious bottlenecks in raw material supplies; but worst of all is the financial situation, which renders all book-keeping so difficult and impedes all attempts, not only to attain all-out production, but even to reach the capacity production of the plants which have been set up with so much pain, trouble and technical skill. It seems that some urgent economic assistance is needed in this direction. Officials of the National Resources Commission say modestly that their efforts have been directed mainly to training cadres of technical men, a policy which will naturally bear fruit after the War rather than now. Nevertheless, her allies ought to find some way of aiding China to attain an all-out industrial production such as they themselves are able to carry on in the war against the Axis.

But in general, the point to be emphasized is that the Exhibition was a triumphant vindication of the technical excellence and competence of Chinese scientific and industrial workers. As such the world should take note of it. Not that the Chinese are late-comers to the world of industry. Their ancestors were using ploughs of iron when ours were using wooden ones, they printed long before Guthenberg, knew of gunpowder long before Schwarz, and made porcelain long before Pallissy. But until modern, theoretical science was born, all such achievements remained purely empirical; and modern industrialization is not, and could never have been, based on purely empirical knowledge. The Chinese, therefore, have to master applied science as a whole, just as Westerners have done. The recent Exhibition showed that they are, what John of Monte Corvino called them four hundred years ago, "di nostra qualitá".

J. B. VAN HELMONT (1579-1644)

By Dr. W. PAGEL

JEAN BAPTISTE VAN HELMONT, the great Flemish natural philosopher, died three hundred years ago, at the age of sixty-five, bringing to a close a life embittered by religious persecution, but rich in inward contentment derived from sincere piety and a magnificent record of discoveries and ingenious conceptions in science and medicine. He devised one of the early thermometers. He proposed a reform of time measurement by the use of the pendulum and devoted much work to the investigation of its laws. He endeavoured to express vital phenomena in chemical terms and thereby became one of the founders of biochemistry. He demonstrated that acid is associated with digestion in the stomach and alkali in the duodenum. He was one of the initiators of modern pathology, which he sought to base on a study of the external agents in relation to local changes in the organs in disease. This led him to a refutation of the "Folly of Catarrh"—the title he gave to one of his treatises—for it was then believed that many diseases were due to a flow of mucus from the brain straight through the base of the skull to all parts of the body, notably to the lungs and joints, causing consumption, rheumatism, pneumonia, gout. He even made practical contributions to clinical medicine, for he examined the specific gravity of urine and demonstrated the presence of carbon dioxide and ferrous oxide in the waters of Spa by means of evaporation.

In connexion with the discovery of 'acid fermentation' in the stomach, it is worth while recalling the theories of Paracelsus (1493–1541), which admittedly stimulated Van Helmont's work. Paracelsus recognized different digestive properties in the various digestive organs, such as mouth and stomach ("Opus Paramirum", III), and described the powerful support of gastric digestion by intake of acid, notably those found in spas[1], but did not regard acid as a normal secretion of the stomach, except in the case of the ostrich, which is thus able to digest metals. The 'fermenting' action of acid, for example, in food, had already been mentioned by Galen[2], but up to Van Helmont's time and for a long time after, 'heat' and 'trituration' were believed to be the actual forces of digestion in the stomach.

Critical evidence has been given[3] of Van Helmont's achievements in chemistry, of the quantitative character of his work, of his extensive use of the balance. These gave him insight into the indestructibility of matter. Thus he showed, for example, that metals are recoverable without loss of weight after solution in acid. He realized, moreover, that when one metal precipitates another from a solution of a salt there is no transmutation. He also made a clear distinction between copper and iron vitriols[4].

Van Helmont studied volatile bodies with particular care. The achievement by which he is specially remembered is the separation from air and water vapour of a "New Entity" which he called "Gas". This "new entity" involved a change in the general concepts of biology, of medicine and indeed of cosmology and philosophy[5]. Such implications emerge with any attempt to restore the original setting in which the discovery was presented.

'Gas' appears first of all to be something 'specific' to the object in which it was contained. It is thus in contrast to volatile bodies such as air and water vapour, of which all objects in Nature may partake[6]. Van Helmont sees gas as the vector of a specificity

which he believed he demonstrated in every being. Moreover, it is by virtue of its specific "gas" that an object is alive. "Life" in this sense means what later Glisson, carrying Van Helmont's conception a step further, called the "Energetic Nature of Substance". This was the point of view of Leibniz's monadology. Van Helmont, Glisson and Leibniz believed in 'forces' intrinsic *in* matter and its finest particles, but not acting *on* it. Thus the unsatisfactory dualism of 'soul' and 'body' was replaced by the idea of specifically different 'biological units' with spiritual and corporeal aspects. This was a kind of 'pluralism' which foreshadows certain modern biological concepts.

Each of these thinkers based his theories on certain scientific experiences of the day. Leibniz had in mind the innumerable organized units which the microscope had revealed in drops of water. Glisson had experience of tissue fibres and visualized intrinsic 'perception and appetite' in their fine anatomical organization, their irritability and formation of sphincters. It is no accident that it was he who discovered the rhythmic entry of bile into the duodenum and the sphincter at the orifice of the common bile duct. Van Helmont regarded the qualitatively different volatile products which he studied as the essence of various objects in Nature from which they were obtained. 'Gas' represented 'disposed' or 'organised matter' in the widest sense. Hence 'gas' as a chemical entity cannot be separated in his writings from its philosophical connotation. This is the stumbling block in his writings for most modern scientific readers. The inseparability of scientific result and philosophical implication applies to his achievements in physiology, pathology and his biological concept of time[7].

Such philosophical implications cannot be ignored in the works of seventeenth century scientific workers. Science was not yet an organized body of specialized subjects associated with the activities of full-time research workers and lecturers engaged in specially directed studies. Its status was, therefore, quite different from that which it came to assume in the following centuries. Nature as a whole, *Philosophia Naturalis* rather than a number of scientific subjects, presented itself to the scientific worker. His activities were bound to cover a much wider field and to be mingled with philosophical elements. It could not be taken for granted that the results of any particular worker were purely scientific or scientific at all, since there was no separation of philosophy and science, of belief and knowledge; though such a separation is the elementary premise of the scientific worker of the nineteenth and twentieth century. In discussing a writer of the time of Van Helmont, it is impossible to avoid discussing the original—philosophical—meaning of concepts which have now become exclusively scientific. "L'Historien des Sciences doit se faire le Contemporain des Savants dont il parle[8]." The case of Van Helmont is no isolated example of this claim.

OBITUARIES

Mr. Frederick Chapman

THE sudden death of Frederick Chapman, a prominent authority on the Foraminifera and a distinguished Australian palæontologist, at his home at Kew, Victoria, on December 10, 1943, within a few weeks of his eightieth birthday, severs almost the last link in the chain of workers who for nearly a century have kept Britain in the forefront of the study of the Foraminifera.

Chapman was born at Camden Town, London, his father being Robert Chapman, who was assistant to Michael Faraday and John Tyndall. At an early age, through the influence of his brother Robert, he became interested in entomology and botany, but his appointment at the age of eighteen as laboratory assistant to Prof. J. W. Judd at the Royal College of Science led to his taking up geology as his life's work. He remained at the Royal College of Science until 1902, when, on the recommendation of Judd, he was appointed palæontologist to the National Museum, Melbourne. He occupied this position until 1927, when he was engaged by the Commonwealth Government as first Commonwealth palæontologist. He retired from his official duties in 1935, but continued to engage in scientific work until his death. From 1920 until 1932 he was part-time lecturer in palæontology at the University of Melbourne. He also occupied a number of honorary positions and served as a member of the International Commission on Zoological Nomenclature for more than twenty years.

Throughout his life, Chapman possessed good health and abundant energy as well as an absorbing interest in his work, and his scientific output was exceptionally large, comprising more than five hundred books and papers. While he had a special interest in the Foraminifera, on which he covered a wider field than any other writer on the group, his publications deal with geology, palæontology and zoology. Of these may be mentioned his papers, "The Foraminifera of the Gault of Folkestone", "New or Little Known Fossils in the National Museum", his reports on the Foraminifera and Ostracoda of the Shackleton and Mawson Expeditions to the Antarctic, and his books, "The Foraminifera", "Australasian Fossils", and "Open Air Studies in Australia". It has been said that in his work in Australia he attempted too much; but, as Prof. J. W. Gregory remarked when Chapman was awarded the Lyell Medal of the Geological Society of London in 1930, "A man single-handed, in charge of a great palæontological collection, cannot however specialize. He has to do what comes to him and not what he would choose. Mr. Chapman loyally and valiantly dealt with an unusually wide range of fossils . . ." Chapman's last work was a paper dealing with the conclusion of the investigation, begun by him nearly fifty years before, of the cores from the borings put down at Funafuti by the Royal Society of London to test the correctness of Charles Darwin's theory of the formation of coral reefs. This is still unpublished.

Chapman's great services to science were recognized by his election as an associate of the Linnean Society of London (1896), the honorary fellowship of the Royal Microscopical Society (1929), the award of the Lyell Fund (1899) and the Lyell Medal (1930) of the Geological Society of London, and other distinctions conferred on him in Australia, New Zealand and the United States. One of the finest tributes to his work

in Australia was paid by the late Prof. T. W. Edgeworth David, who said: "No one in Australia since the time of Robert Etheridge, Jnr., has more enriched our knowledge of the past forms of life in Australia than has this worker, whose ability is matched to a marvellous industry".

Chapman was personally a charming companion and loyal friend. He was ever willing to give those who sought his aid the benefit of his wide knowledge and great experience. Blessed with an even temperament, he had an old-world courtesy which never deserted him. His wide circle of correspondents throughout the world particularly will regret his passing. W. J. PARR.

Mr. Arthur Earland supplements this account as follows:

Of recent years, much of Chapman's work on the Foraminifera was done in collaboration with Mr. W. J. Parr, including "A Classification of the Foraminifera", published in 1936, which is probably the best and most natural of the many efforts to deal with this difficult subject. They were also jointly responsible for the long-delayed report on the Foraminifera of the Australasian Antarctic (Mawson) Expedition of 1911–14, published in 1937.

Mr. C. B. Rickett

C. B. RICKETT, who died on April 8 at the age of ninety-two, was the last of a triumvirate of British ornithologists who did so much for the study of Chinese ornithology at the end of the nineteenth and beginning of tho twentieth centuries.

Charles Boughey Rickett was born in Hong Kong on December 10, 1851, and was the son of John Rickett, who was in the service of the East India Company. At an early age he joined the Hong Kong and Shanghai Banking Corporation, and after serving in branches in India, Japan and Java, was appointed agent at Penang in 1885, and five years later was transferred to Foochow. He had been collecting birds while in the Straits, but he did not take this up seriously until he arrived at Foochow. J. D. La Touche had already written about the birds of that area, but Rickett, after four years work, was able to add much additional information.

The two ornithologists became great friends and wrote more than one joint paper. Through La Touche, Rickett came to know F. W. Styan, who was engaged in the tea trade and an authority on the birds found in the Yangtse Valley. The three carried out a joint trip to the hills north of Foochow which resulted in several interesting discoveries; later they combined to send Chinese collectors to less accessible parts of China—with valuable results.

Rickett was a good field observer, and his papers contained many interesting notes. His collections, amounting to some four thousand skins and a thousand eggs, and a considerable number of mammals, were presented to the British Museum. After his retirement he lived in England and finally settled in Reading. He was a very regular attendant at the monthly meetings of the British Ornithologists' Club up to his eightieth year, and was one of the best known and popular members. N. B. KINNEAR.

WE regret to announce the following deaths:

Prof. Wilhelm von Mollendorf, professor of anatomy and director of the Anatomical Institute at the University of Zurich, aged fifty-seven.

Dr. Daniel M. Molloy, field director in Central America for the International Health Division of the Rockefeller Foundation, on January 29, aged sixty-one.

Mr. J. R. Norman, deputy keeper in the Department of Zoology, British Museum (Natural History), an authority on fishes, on May 26, aged forty-five.

Prof. S. Oberndorfer, director of the Institute of General and Experimental Pathology and of the Cancer Institute of Istamboul University, on March 1.

Prof. Wolfgang Ostwald, professor of colloid chemistry in the University of Leipzig, aged sixty.

Sir Herbert Thompson, Bart., the well-known Coptic scholar, on May 26, aged eighty-four.

NEWS and VIEWS

Association of Teachers in Technical Institutions

SOME problems likely to face the technical colleges as a result of the application of the 1944 Education Bill formed the main theme of Mr. H. Wragg's presidential address to the Association of Teachers in Technical Institutions at the thirty-fifth annual conference. After indicating the needs of democracy for a knowledgeable and discerning electorate and ability "to create and develop ideas which will ameliorate the life of the community", Mr. Wragg surveyed the deficiencies of past educational legislation in so far as it touched the technical field, and welcomed the recognition given to the present junior technical schools by their being placed on the same footing as the grammar and modern schools. He directed attention to the problems involved in providing more school buildings and additional teachers to meet the expanding situation. The erection of new buildings takes considerable time but "time and cost of manufacture and erection are greatly reduced when many things of the same pattern are required". Mr. Wragg felt that teachers of building would find in this problem great scope for their energies. Already new junior technical schools of building have been opened. As to teachers, the vast number required (estimated at 50,000–100,000) "can only be secured if the profession is attractive to new entrants"; and revised salary scales are now under discussion (see also p. 663 of this issue). The need for close co-operation of technical colleges in compulsory part-time education from fifteen to eighteen was indicated, and the hope expressed that part-time day release would extend (voluntarily) until the age of twenty-one. Opportunities should be seized for expanding full-time courses for suitable students. The new Bill gives unsurpassed opportunities for local education authorities to erect "an all-embracing educational structure on the firm broad basis of primary and secondary education for all", with towers corresponding respectively to the universities and the technical, commercial and art colleges.

The Nutrition Society

THE science of nutrition expanded so much of recent years that it was no longer adequately covered by existing societies. In July 1941, therefore, a proposal to form a nutrition society was put forward, under the auspices of the heads of various well-known institutes engaged in research on nutrition in Britain, which would follow on the lines of the Physiological and Biochemical Societies, although there was no question of publishing a journal at that time. At the first meeting in the same month, it was felt that the main object of the new Society should be to form a common meeting place for workers in the various fields of nutrition, namely, physiological, biochemical, agricultural, medical, sociological, economic and public health, and that it would be useful during the War to have a separate Scottish Group. The Society had not long been founded when it became apparent that the value of its proceedings would be enhanced by their reaching an audience wider than that which actually participated in its meetings. The Royal College of Physicians, impressed with the advantage which the medical profession might reap from gaining immediate access to the records of the meetings of the Society, made an offer which enabled the financial and other difficulties standing in the way of publication during war-time to be overcome. Accounts of the first meeting and of English and Scottish Group meetings up to May 30, 1942, are now published (*Proc. Nutrition Soc.*, 1, Nos. 1 and 2, 1–112; 1944) and include "Evaluation of Nutritional States; Food Production, Distribution and Supplies in Relation to Human Needs", and "Problems of Collective Feeding in War Time". The second double number will contain reports of meetings on dehydration, food supplies, trace elements and diet in pregnancy and lactation.

British Medicine and the Göttingen Medical School

IN a recent paper (*Bull. Hist. Med.*, 14, 449; 1943) Prof. Max Neuburger remarks that during the eighteenth century inadequate facilities for teaching and research prevented most of the medical schools in Germany from furthering either medical training or scientific research. On the other hand, the medical school at Vienna and the Medical Faculty at Göttingen were remarkable exceptions, and owed their celebrity to two famous pupils of Boerhaave, namely, Gerhard van Swieten at Vienna and Albrecht v. Haller at Göttingen. George II, who founded the University of Göttingen in 1734, invited Haller to fill the vacant chair of medicine, which included anatomy, surgery and botany. Haller had previously spent some time in London, where he made the acquaintance of several English physicians and surgeons such as Sir Hans Sloane, John Pringle and William Cheselden, and frequently quoted British writers, notably Stephen Hales, John Mayow and Thomas Willis, in his own works. During the seventeen years when he resided at Göttingen, he exercised a great influence on the University, being responsible for the erection of an anatomical theatre, a botanical garden and a lying-in institution. He also founded a scientific society of which he was the first and permanent president, and a scientific journal to which he made more than a thousand contributions. Between 1739 and 1744 he completed the six-volume edition of Boerhaave's "Institutiones", for which he was elected a foreign member of the Royal Society. He was also author of numerous other works on anatomy, physiology, medicine, surgery and botany. In 1739 he was appointed physician in ordinary to George II, who conferred a knighthood upon him and made him one of his consultant physicians. Owing to reasons of health, he left Göttingen for Berne in 1753. Many of Haller's successors at Göttingen, as Prof. Neuburger points out, had studied in London. Among them may be mentioned Roederer, Sömmering, Thomas Young and Blumenbach.

Quekett Microscopical Club

FOR some eighty years, the Quekett Microscopical Club has taken a leading part in the development of microscopy, and many leading research workers have been included on its membership roll and have recorded the results of their work in its journal. Thanks to the courtesy of the Royal Society, the Club, which at present has a membership of nearly three hundred and fifty, is now meeting at Burlington House, Piccadilly, where the Club's library and slide cabinet are again available, after having been removed to safety in the country during the last four years. Meetings are held as originally, on the second and fourth Tuesday in each month, the earlier being an ordinary (lecture) meeting, whereas the latter is devoted to the exhibition of specimens, apparatus and general discussion. On Saturday afternoons, collecting excursions are conducted and visits to places of interest to microscopists are arranged. The affairs of the Club are managed by two secretaries: Mr. E. P. Herlihy, 76 Brook Green, London, W.6, dealing with business matters, and Dr. James Davidson, 41 Brampton Grove, London, N.W.4, with scientific matters and papers.

Chagas's Disease in Brazil

IN a recent paper (*Bol. Of. San. Panamericana*, 22, 773; 1943), C. Chagas, jun., states that during the thirty-three years since Chagas's disease was discovered in a small area in the State of Minas Gerais, Brazil, the disease has been found to have spread throughout North and South America. As regards the parasitology, it is now universally accepted that Schizotrypanum is the cause of the disease. Studies are now being made to obtain more complete data regarding insect vectors, prevalence of the disease and animal carriers of the virus. Among domestic animals, cats and dogs take the first place as carriers.

Work at the Madrid Observatory

BULLETIN 9 from the Madrid Observatory deals first of all with the photographic and visual observations of Nova Lacertæ 1936, made at the Observatory. The photographs were obtained by means of a camera of short focus used in conjunction with the Grubb photographic equatorial, which has an aperture of 16 cm. and focal length 80 cm. The method employed for determining the magnitude of the nova was by measuring the diameters of the focal images, and applying the formulæ of Charlier and Parkhurst, adopting the mean from both formulæ. Nine comparison stars of various spectral types were used, and the results are shown in Table 2, the observations extending over the period June 21–July 17, 1936. In addition to the photographic observations, about 500 visual observations were made between June 18 and July 20, the results of which are given in Table 3, and from these the colour-index was deduced. This varied according to the spectral type of comparison star; for Class $F0$ it was 0·30 and for Class $B8$ it

was $-0 \cdot 08$, and was practically zero for Class $A0$. A curve shows the results of the photographic and visual determinations of magnitudes, the photographic magnitudes being represented by circles which lie close to the visual magnitude curve.

Similar work was done with Nova Herculis 1934, the observations extending from December 16, 1934, to April 30, 1935, and the light curve of the nova between these dates is given, circles representing the photographic magnitudes as in the case of Nova Lacertæ. A maximum difference occurred about the middle of January, this difference (photographic—visual) being 0·5 mag. It was found impossible to deduce the value of the colour-index, but it is hoped that this will be done when further data are available from various scientific journals, thus enabling comparisons to be made with the work at the Observatory of Madrid.

Bulletin 10 from the Observatory deals chiefly with solar prominences observed at the University of Valencia during 1938, and is a continuation of the 1937 observations recorded in a previous issue of the bulletin (see NATURE, **151**, 405; 1943). In addition to a description of the solar spots observed in 1938, the issue contains the positions of Comets van Gent, Whipple-Bernasconi-Kulin and Whipple-Fedtke, determined from photographic observations.

Aeroplane Compass

IN *Sky and Telescope* of January 1944 there is a description of the Gyro Flux Gate Compass System, which has overcome many difficulties for air navigators. It combines the action of the flux of the earth's magnetic field with a gyroscope designed to keep it horizontal in spite of the movements of the aeroplane. It is very much more sensitive than the ordinary compass, and it can be operated close to the earth's magnetic poles, if necessary. The existence of the instrument has been revealed recently, because it is believed that some of the compasses have fallen into the hands of the enemy, though it seems certain that he cannot produce it in great quantity during the present War. A description of the instrument is given; but the technical details are too complicated to be dealt with here. Its practical utility can be judged from the fact that its reading of true compass directions and its reliability under varying conditions have contributed to reduce the number of accidents due to uncertainties in navigation.

Transmission Line Supports

IN a paper on reinforced concrete supports read recently in London by Messrs. E. C. Neate and W. F. Bowling before the Institution of Electrical Engineers, consideration is first given to previous work done in Great Britain, and this is followed by a discussion of the requirements of a reinforced-concrete transmission-line pole. Details of experimental poles are given with an analysis of the results of tests to destruction. A graphical method of design is developed, and sufficient information is provided to enable future work to be undertaken on the bases established. An expression is obtained for the deflexion of a pole under load, and it is shown that deflexion cannot be taken as a criterion for proof-test purposes. The authors discuss fabrication and erection methods, and the paper concludes with a survey of the advantages and disadvantages of the concrete pole, reference being made to a *questionnaire* issued to a number of users in Great Britain.

St. Louis Chapter of the Society of the Sigma Xi

THE St. Louis Chapter of the Society of the Sigma Xi was installed at St. Louis University on March 16 by Prof. Harlow Shapley and Prof. George A. Baitsell. Forty members and three associate members formed the petitioning group. Prof. Shapley spoke on "Co-operation in Research", and later, Prof. Peter Debye gave the Sigma Xi Lecture, "The Magnetic Approach to Absolute Zero". Chapter officers elected for the following year were Kermit Christensen (president), Charles H. Neilson (vice-president), Arthur G. Rouse (secretary) and Alfred H. Weber (treasurer).

Announcements

THE Albert Gold Medal of the Royal Society of Arts has been awarded to Sir Henry Tizard, president of Magdalen College, Oxford, and formerly rector of the Imperial College of Science and Technology, distinguished for his scientific work in the development of aircraft (see NATURE, Aug. 1, 1942, p. 148).

THE first award of a gold medal founded in memory of Dr. Bimala Churn Law by the Indian Association for the Cultivation of Science has been made to Sir Henry Dale, president of the Royal Society. The award is given for important contributions to science including medicine.

PROF. JOHN MACMURRAY, Grote professor of the philosophy of mind and logic in the University of London, has been appointed professor of moral philosophy in the University of Edinburgh in succession to Prof. A. E. Taylor.

DR. S. W. WOOLDRIDGE, reader in geography in the University of London (King's College), has been appointed to the chair of geography in the University tenable at Birkbeck College, in succession to Prof. E. G. R. Taylor.

AT the anniversary meeting of the Linnean Society of London held on May 24 the president, Mr. A. D. Cotton, delivered a presidential address, "The Megaphytic Habit in the African Tree Senecios and other Genera". The following were elected officers for the year 1944–45: *President*, Mr. A. D. Cotton; *Treasurer*, Colonel F. C. Stern; *Deputy Treasurer*, Dr. B. Barnes; *Secretaries*, Dr. B. Barnes (botany) and Dr. Malcolm A. Smith (zoology); *Members of Council*, Prof. A. J. E. Cave, Captain Cyril Diver, Dr. Edward Hindle, Mr. A. A. Pearson, Lieut.-Colonel R. B. Seymour Sewell.

LORD KEMSLEY has made a gift to the University of Sheffield to provide, during a period of seven years from its first coming into operation, an annual travelling fellowship of £400 a year. The fellowship will come into operation as soon as circumstances allow its conditions to be fulfilled. Candidates must be unmarried men and British subjects by birth holding the degree of bachelor of the University of Sheffield and who since graduation have not taken up other full-time work than study or research in a university in the United Kingdom. The main condition of tenure is that the Fellow shall actively study at first hand the ways of a good life and of thought in the country selected, and shall become efficient in speaking and reading its language. Candidates will generally be selected from the Faculty of Arts. No applications will be accepted before a date to be announced in due course by the University of Sheffield.

LETTERS TO THE EDITORS

Vertical Section of a Coral Atoll

Recently, Captain A. G. N. Wyatt, R.N., in one of H.M. ships, visited Fadiffolu Atoll in the Maldive Islands, and opportunity was taken to run a line of soundings across the atoll and to carry it on into deep water to a distance of some 5¾ miles from the rim.

An interesting feature of this work was the control. While in sight of the islets it was, of course, possible to fix the position of the soundings by cross bearings, but it is probably the first time that such a section has been controlled by taut-wire measurement over the rim of an atoll, so that it can be stated that the depths which were recorded continuously by echo soundings show a completely accurate determination of the contour of the sea-bed from within the atoll, where depths of rather more than 20 fathoms were obtained, into deep water of more than 1,000 fathoms.

The accompanying sketch is from Admiralty Chart No. 3324, and the section below shows the form of the sea-bed.

J. A. Edgell.

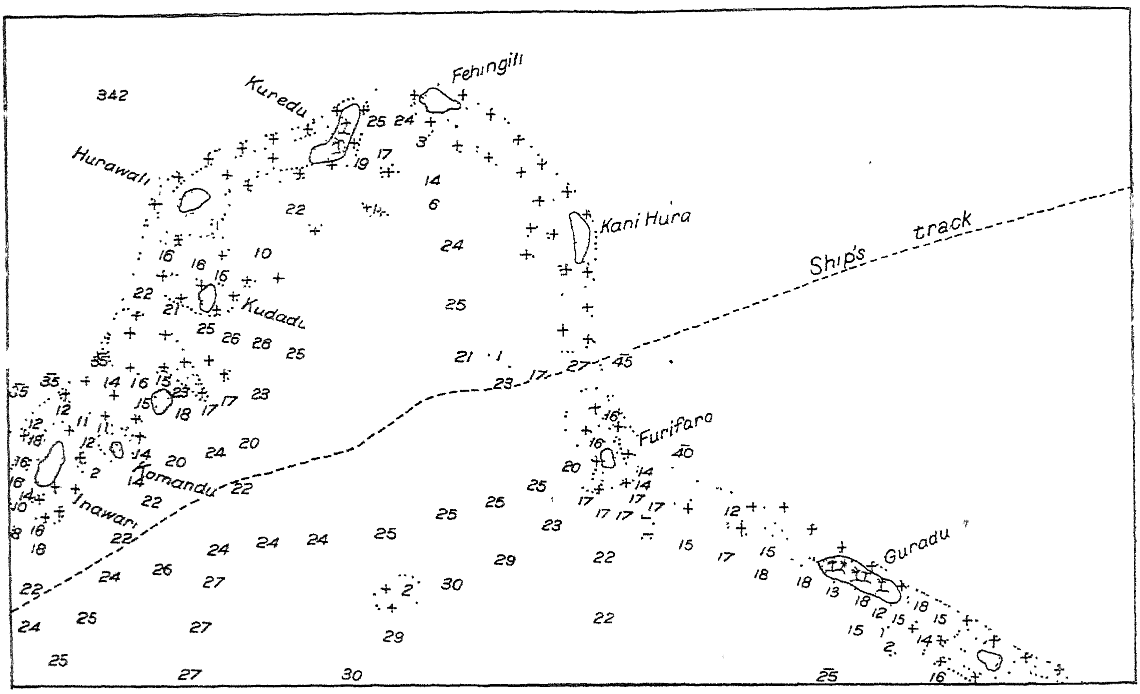
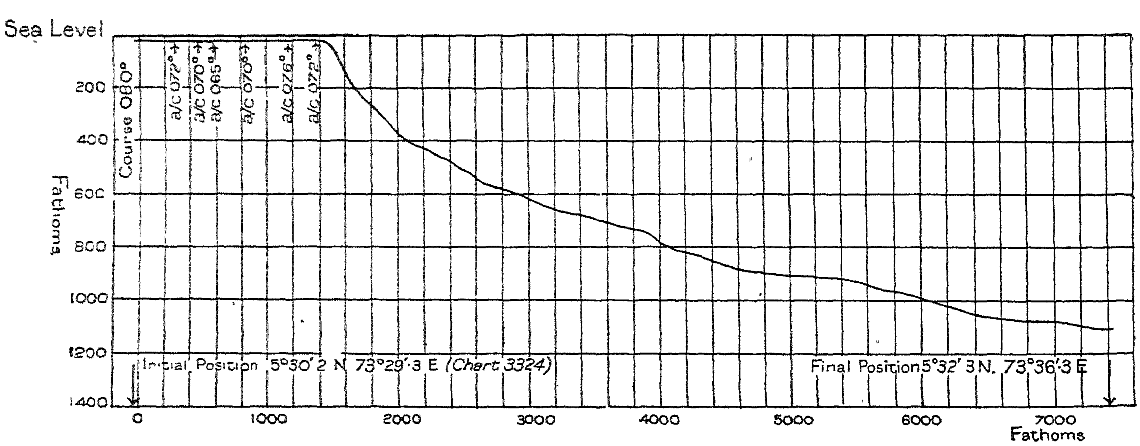
Admiralty, London, S.W.1.

Fatigue in Selenium Rectifier Photocells

Fatigue in selenium rectifier photocells is generally marked by a falling off in the current output, during exposure to steady radiation, of cells which have been kept for some time in darkness. The rate of decrease is greatest initially and diminishes until a practically steady current is attained after perhaps several hours. If the cell be again darkened, recovery



Maldive Islands. Fadiffolu Atoll (northern portion)



Maldive Islands. Fadiffolu Atoll. Section drawn on a line 072° through the N.E. entrance to the lagoon.

takes place. According to most investigators, recovery is a much slower process than fatigue.

Elvegard, Lindroth and Larsson[1], and more recently R. A. Houstoun[2], found that the degree of fatigue depends on the spectral quality of the radiation. They attempted no explanation of their results in terms of other properties of the cells, however. Incidental observations made at the National Physical Laboratory, during measurements of the spectral sensitivity of a number of cells, afford some new results of which a tentative explanation is possible.

It was found that: (1) When cells were exposed to radiation of wave-length greater than $0\cdot64\,\mu$ the current fell by 10 per cent in a few minutes. When the cell was afterwards darkened, recovery occurred at a similar rate. (1*a*) A few seconds exposure to overcast daylight depressed the sensitivity for wave-lengths exceeding $0\cdot64\,\mu$ by 20–25 per cent. Recovery was fairly rapid during subsequent tests with red light of comparatively low intensity. (2) With rare exceptions fatigue did not occur, or was barely detectable, with radiation of wave-lengths less than $0\cdot62\,\mu$. (3) Effects (1) and (2) were independent—exposure to light of either of the two spectral regions had no effect on the result of subsequent exposure to light of the other region.

In these experiments the cells were exposed to radiation within narrow spectrum bands (width about 100 A.). The whole of the cell surface was exposed. The resistance of the external circuit was effectively zero and the photocurrent was about 1 microamp. These conditions, and the results obtained, are not in all respects the same as in the experiments of the investigators mentioned. In particular, the photocurrent was much smaller in the present experiments. It was found, however, that the behaviour described could also be observed when the photocurrent was about 50 microamp. To show this, the cells were exposed to a tungsten lamp, signal-green and signal-red glasses being used to isolate the two spectral regions.

The behaviour described here is probably connected with the extent of penetration of the radiation into the selenium. Selenium has a fairly high transmission for wave-lengths greater than $0\cdot64\,\mu$, and is practically opaque for wave-lengths less than $0\cdot60\,\mu$. This would account for the different behaviour observed on exposure to the two spectral regions, for the photoelectric action would take place in layers situated at different depths depending on the penetration of the radiation. Moreover, we should expect the fatigue to be greatest when the action is in the deeper layers and least when only the superficial layer is concerned, the effect observed in our experiments.

The cells used in our experiments were supplied by Messrs. Evans Electroselenium, Ltd.

Mathematics of Biological Assay

BIOLOGICAL assays may be divided into two main classes. In the first, which we may call Type I, the 'potency' of the test material, as compared with that of a standard preparation, refers only to its relative ability to produce certain effects in the experimental animals, no assumptions being made as to the substance or substances responsible for the effects. An example is the testing of extracts from plants for their insecticidal power. In Type II, however—and this must now be the larger class—the response of the experimental animals is used to estimate the content, in units of some kind (which may be either of an *ad hoc* nature or actual units of weight) per unit weight of test material, of a single substance producing the response in question. Into this category fall, for example, most assays of vitamins.

My previous letter[1] on the theory of the 4-point experimental design was intended to show that the method was of both wider applicability and greater accuracy than N. T. Gridgeman[2] had assumed. I was at the time, I admit, thinking only of Type II assays. D. J. Finney has now rightly pointed out[3] that in certain assays (which, as will be seen later, must be all of Type I) the method may be quite invalid. I feel, however, that some readers might be unduly frightened off the 4-point method by Mr. Finney's letter, as much as some others might be led into unjustifiable use of it by mine. It is perhaps worth while, therefore, to consider further the criteria to be satisfied in order that the 4-point method may be valid.

All biological assays begin by being of Type I. They are transferred to the Type II group as soon as the progress of knowledge makes it plausible to assume that the responses of experimental animals dosed with the standard preparation and those dosed with the test preparation are qualitatively identical and caused by the same factor F in both preparations; and that this factor, whether chemically an element or a compound, is single in nature and uniquely responsible for the effect. This assumption must be regarded as experimentally established before the conclusion "This material is 10 times more potent than the standard", which is typical of Type I assays, can be translated into "This material contains 10 times more of the factor F than does the standard", equally typical of Type II assays. (Whether or not the further step to "This material contains U units of the factor F per gram" is made is irrelevant.) Moreover, the assumption in question is inherent in the experimental design of any normal Type II assay—in the interests of brevity the reader is left to check this point for himself.

But if the experimental response to dosage is caused by a single factor F and by nothing else, then the test and standard preparations must behave as solutions of the factor F, of different concentrations, in a biologically inert diluent; and the relation between the response Y and the log-dose X, whatever its form may be, must be the same in both cases. In fact, if the doses are measured not in terms of the weight of preparation given but in units of the factor F contained therein, all the experimental data are points on the same curve. In so far as this is not true, the translation of 'potency' into 'content of factor F' *will be in error, whether the method of assay adopted was the 4-point one or not.* In any valid Type II assay, however, there are not merely (to quote Mr. Finney) "strong *a priori* reasons for believing that the standard and test preparations have response curves of identical form"—this assumption is, as just stated, fundamental to the design of the experiment and the interpretation of the results. In such cases, the 4-point method of assay correctly estimates the relative potency of the test and standard preparations, provided that the relationship between Y and X is of the form

$$Y = a + bX + cX^2,$$

which, at least over the range of doses employed in

practice, may justifiably be assumed to be true. (Even if there are cubic and higher terms in X, the 4-point method will be in error to an extent which is insignificant compared with the irreducible error of all biological assays.)

Summing up, therefore, a 4-point method of assay is perfectly justifiable, and will give an accurate estimate of the relative potencies of two preparations, in all cases where the response of the experimental animals is assumed to be caused by a single factor present in both and to be uninfluenced by any other constituent of either. In assays in which this assumption is not made, the 4-point assay *may* still be valid if there are cogent reasons, derived from previous work, for assuming that the standard and test preparations have response curves of identical form. In all other cases, the 4-point assay is unjustifiable, will probably result in grave error, and should not be employed.

Mr. Finney has seen this letter and is in full agreement with it. He suggests, however, that attention should be directed to the desirability of so arranging the dosages that the responses to the test and standard preparations are not very different. A working rule, which provides a good factor of safety in avoiding certain possibilities of error, is to regard as only tentative any conclusions drawn from a 4-point assay unless the response to one of the two doses of the test material falls between the responses to the two doses of the standard preparation.

The conclusion of Mr. Finney's letter to me might fittingly conclude this letter also. "I think that the decision on a suitable assay procedure is mainly one for the biologist or chemist involved, not a matter of abstruse mathematical theory, and he must make this decision in the light of his experience and knowledge of the material in question."

Fluctuations in the Porosity of Egg-Shells

DURING the course of an experiment designed to study the effect of different levels of dietary calcium on various egg-shell characteristics, measurements were made of the porosity of egg-shells. Eggs were collected from twelve birds in all during a period lasting from mid-December to mid-January. At first, four birds received a high-, four a medium-, and four a low-calcium diet; later, all twelve received the medium-calcium diet. A basal ration low in calcium was used, and to this was added 8, 4 and 0 per cent of calcium carbonate to give the high-, medium- and low-calcium diets respectively.

Porosity was measured by calculating the loss in weight in milligrams per day per square centimetre of surface area under standard conditions of humidity and temperature, total surface area being calculated from Dunn's formula[1], as modified by Mueller and Scott[2]. The porosity value obtained will be referred to as the porosity coefficient.

Considering birds on the high- and on the medium-calcium diets, it was observed that in thirty-five out of forty-one clutches produced, the first egg of the clutch had a porosity coefficient less than that of any of the remaining eggs in the clutch—a clutch being here defined as a series of eggs laid on successive days, with one or more days of rest from laying between the clutches.

As examples of these variations in porosity coefficients, values for bird 2, which was first on the high- and then on the medium-calcium diet, and for bird 5, which was on the medium-calcium diet throughout, are given in Table 1.

TABLE 1.
BIRD 2.

Clutch No.	1	2	3	4	5	6	7
Days of rest before clutch	1	1	1	1	1	2	2
Porosity coefficients of successive eggs in clutch 1st	1·84	2·00	1·85	2·22	2·05	1·99*	1·82
2nd	2·67	2·49	2·28	2·35		2·22	2·37

4th	2·32	2·41				2·19	2·27
5th						2·30	

*First egg on medium-calcium diet.

The birds on the low-calcium diet soon ceased to lay, and their calcium metabolism was profoundly disturbed, as shown by the gradual thinning of the shells and a general increase in porosity coefficients; however, even these birds displayed a similar tendency, though less pronounced, for the first egg of a clutch to have a smaller porosity coefficient than succeeding eggs of the clutch. Porosity coefficients for bird 12 are shown in Table 2.

Days of rest before clutch		1	1	1
Porosity coefficients of successive eggs in clutch	1st	3·52	2·30	2·69
	2nd	2·36	2·78	4·36
	3rd	2·84	3·26	

It should be clearly understood that the low porosity coefficient of the first egg of a clutch is not caused by a thicker shell. A large number of shell thicknesses have been measured, and there is no indication of a relationship between shell thickness and porosity coefficients, except, as mentioned above, where shells become abnormally thin on the low-calcium diet.

Common and Hale[3], and Tyler and Willcox[4], while expressing their views somewhat differently, are in substantial agreement concerning mobilization of bone calcium by laying hens. They have suggested that the bones of laying hens have two types of calcium reserve from which the bird can draw when the calcium absorbed from the food is insufficient to provide for all the shell calcium. The more readily

mobilized reserve has a relatively high calcium–phosphorus ratio (there is evidence that the ratio, under certain conditions, may be infinitely high, that is, that calcium may be withdrawn without a corresponding withdrawal of phosphorus), while the less readily mobilized reserve has a relatively low calcium–phosphorus ratio. The chief source of bone calcium for the first egg of a clutch is the more readily available reserve, whereas the relatively less available reserve is drawn upon to a progressively greater degree for the succeeding eggs of the clutch.

It is too early yet to link up the differences in porosity with this conception of different types of bone calcium, but the possible connexion should be borne in mind when attempts are made to explain these porosity changes.

It is hoped to publish a fuller account of this work at a later date.

Effects of X-Rays on Erythrocytes Irradiated *in vitro*

IRRADIATION of erythrocytes with X-rays *in vitro* causes hæmolysis. The dose of X-rays required to obtain complete hæmolysis is influenced by the concentration of the erythrocyte suspension and by the medium. A state of resistance to hæmolysis results when a dose of two million r. is given to an erythrocyte concentration of 0·1 per cent or less in normal saline[1]. The question arises, whether these erythrocytes are resistant to other hæmolysins or only to the X-rays producing this stable state.

To answer this question, experiments were undertaken in which erythrocytes made resistant to hæmolysis by X-ray irradiation were exposed to the hæmolytic effect of light and saponin respectively.

(1) Human or rabbit erythrocytes in 0·1 per cent suspensions in normal saline in hanging drops under mica slides were irradiated with doses of 2 million *r* (35 kV. 15 milliamp. copper anode 3 cm. distance). After 24 hours there was no hæmolysis. Then after addition of eosin solution to the irradiated drops and to non-irradiated control drops both were exposed to sunlight. Hæmolysis occurred in the control drops after 10–20 min., while in the X-irradiated drops no hæmolysis took place after 1–2 hours.

(2) Solutions of saponin were added in different concentrations to erythrocytes prepared and irradiated in the same manner as in the foregoing experiments. In non-irradiated control drops, addition of one drop of saponin solution (1 : 15,000) caused hæmolysis in about 5 min., while concentrations of 1 : 3,000 were not hæmolytic to the pre-irradiated erythrocytes after 24 hours.

The results of these experiments suggest that two different effects of X-rays on erythrocytes are possible, one of which causes complete hæmolysis, whereas the other, on the contrary, causes the erythrocytes to become resistant to the hæmolytic effect of X-rays, light or saponin.

Whether one or the other effect takes place depends on the concentration of the erythrocyte suspension in normal saline and the dose of X-rays. The resistance to hæmolysis fails to appear if serum is added to the normal saline or if the erythrocytes are irradiated in glucose solution.

Vitamin C in Plants

'Nasturtium' (*Tropaeoleum majus*)

THE nasturtium, *Tropæoleum majus*, a native of Peru, flourishes throughout New Zealand. The leaves, which are used as a salad food, are very rich in vitamin C, the concentration ranging from 200 to 465 mgm. per 100 gm. in the samples tested. As a rule, the leaves of any particular plant show much less variation than this, although small leaves tend to have higher values than large leaves. Stalks contain 100–160 mgm. per 100 gm. and are therefore also a rich source. Little or no dehydroascorbic acid is present, although the ascorbic acid oxidase is exceedingly active in disintegrated tissues.

The ascorbic acid was titrated visually in 1 per cent metaphosphoric acid extracts with dichlorophenolindophenol solution. That the reducing properties of the extract are correctly attributed to ascorbic acid is proved by the rapid enzymatic oxidation which takes place in extracts unless prevented by boiling, or addition of metaphosphoric acid, etc. Also, a 60 per cent yield of pure dinitrophenylosazone of dehydroascorbic acid was obtained from an extract made with boiling water, oxidized with iodine and treated with dinitrophenylhydrazine.

An extract for addition to the diet of babies is readily prepared by adding nasturtium leaves to boiling water until no more can be immersed, boiling three minutes longer and draining. This extract normally contains more than 150 mgm. of ascorbic acid per 100 ml., and sealed away from air is fairly stable. It has not the pungent taste of the fresh leaves, this being lost during the boiling.

The nasturtium is a particularly suitable plant for investigation of ascorbic acid distribution, synthesis, etc., and merits more detailed study.

I wish to thank Dr. Guy Chapman for the suggestion that the nasturtium should be examined for vitamin C, and also Mr. K. Griffin, Government analyst, Auckland, for his interest and encouragement.

Iris (*Iris germanica*)

THE communications that have appeared in NATURE during the past few years in which rose hips, pine needles, etc., have been suggested as sources of vitamin C, prompt me to direct attention to the leaves of the common European iris (*Iris germanica*) as a superior material from which this vitamin can

be readily prepared in substantial quantity. Unlike fruits, the ascorbic acid of which increases as they ripen, the leaves of most plants contain the largest amount when young[1]; most of the vitamin rapidly disappears from leaves as the plants mature. With Iris, however, the ascorbic acid content of fresh undried leaves, which is 0·6 per cent in the spring, does not fall below 0·3 per cent as the season advances. Few plant materials contain as high a concentration as that found in Iris leaves even at the end of the season (at least in the vicinity of New York City). The leaves are heavy and can be cut with little injury to the root-stalks. The vitamin is separated from the gums and other substances present in press juice far more easily than from any other source we have used[2].

Indian Gooseberry (*Phyllanthus emblica*)

THE need at the moment, especially of the Fighting Forces, for vitamin C has provided the urge for establishing more natural sources rich in this vitamin. Recent search has revealed that walnut[1], rose hips[2] and parsley[3] are among the most potent. The earlier, already familiar, sources are cited in Thorpe[4]. I wish to direct attention to the existence of another rich source, namely, the Indian gooseberry, discovered more than eight years ago, but missed by subsequent workers abroad and recently rediscovered by Chen *et al.*[5], from China.

In a general investigation on the vitamin C content of Indian plant materials, undertaken by me early in 1935 at the Biochemical Laboratory, University of Madras, in collaboration with Dr. M. Damodaran (senior author), it was observed and reported that the Indian gooseberry, *Phyllanthus emblica* L., contains as much as 290–468 mgm. per cent of the vitamin[6]. According to later workers in India and in the East Indies, the vitamin content of this fruit is even higher: 540 mgm. per cent[7], 720 mgm. per cent[8] of the fresh pulp and 921 mgm. per 100 ml. of the juice[5]. In the original publication[6] it was also reported that the gooseberry fruit, unlike most other plant sources, has the merit of possessing a mechanism capable of protecting ascorbic acid from oxidation, so that the vitamin remains largely intact, even in the desiccated fruit.

The fruit, it is understood[9], is now being utilized by the Food Department of the Government of India for making edible preparations intended to meet, in some measure, the vitamin C requirements of the Indian Fighting Forces. Khan[10] has reported that the gooseberry fruit has been found very useful in the treatment of cases of human scurvy in the Hissar famine of 1939–40. History has it that an attack of scurvy in the Indian army at Nassirbad in Rajputana in 1837 was treated successfully with an extract of the dried fruits[11]. The fruit is known in Hindi as *amla* and the tree is widely distributed in India and Burma.

Early Human Embryos

WE read with interest the short account of the nine–ten day human embryo described by Prof. Francis Davies in NATURE of April 15. This embryo is obviously of great importance and value to the study of early human development, in which such significant advances have been made in the past few years. Prof. Davies compares his specimen with the human ovum *Wi*-8004 described, in a preliminary communication, by Rock and Hertig[1], and he states that "these two ova represent the earliest specimens of fully implanted human ova yet discovered". In fairness to Drs. Hertig and Rock, who have made such valuable contributions to this field of embryology, we think it should be pointed out that one of the ova (*Mu*—8020) described by them is estimated to be 7·5 days old and is in the earliest stage of human intra-uterine development so far described. This ovum is, of course, at a very much earlier stage of development than that described by Prof. Davies. Even the next older specimen of Rock and Hertig (*Wi*—8004), the one to which Prof. Davies refers, is not, unlike Prof. Davies's specimen, completely implanted. To quote Rock and Hertig: "the defective endometrial epithelium has been partially repaired and is in the process of closing the defect created by the implanting ovum". A comparison of the photograph of Prof. Davies's specimen with the photograph of *Wi*—8004 in Rock and Hertig's communication leaves us in no doubt that the former is in a more advanced stage of development and of implantation.

[1] Rock, J., and Hertig, A. T., *Amer. J. Obstet. Gynecol.*, **44**, 973 (1942).

Rock and Hertig[1] explicitly described their 7·5-day ovum (*Mu*—8020) as "implanted on" the endometrium; that is, this ovum has only just begun to embed itself and a large part of the ovum is still freely exposed in the uterine cavity. On the other hand, they referred to their older ova (including the 9·5-day ovum, *Wi*—8004) as "implanted within", "embedded in" the endometrium. In the limits of a short letter, I thus deliberately confined my comparison to "fully implanted" specimens, by which I mean specimens in which no part of the embryonic tissues is exposed freely to the uterine cavity. If completeness of endometrial epithelialization is to be the criterion determining whether an ovum is

fully implanted or not, then my specimen is not so far advanced *in this respect* as the *Wi*—8004 ovum, in that no surface epithelialization has yet commenced in my specimen, but the embryonic tissues are separated from the uterine cavity by the maternal fibrinous elements of the operculum. This process of epithelialization evidently takes a considerable time, since it is not complete even in the 11·5- and 12·5-day Hertig-Rock ova[2], by which time the "fully-implanted" ovum has undergone considerable advance in development beyond the stage shown in my specimen.

But such trivialities mask the important principle that the various elements in human ova of approximately the same age may show considerable differences in the stage of development which they have attained; such has been shown also in macaque embryos by Heuser and Streeter[3]. Whereas the general organization of my specimen is similar to that of the 9·5-day Rock–Hertig ovum (*Wi*—8004), some features of the latter are more developed (for example, partial surface epithelialization, two-layered endoderm), and some are less developed (for example, total size of ovum, thickness of trophoblast) than in my specimen. I have discussed the above points fully in a paper I have submitted for publication elsewhere.

I therefore still maintain that "these two ova represent the earliest specimens of fully implanted human ova yet discovered", and that the detailed differences between them are compatible with their being approximately the same age. I naturally share the admiration of Profs. Hamilton and Boyd for the work of Rock and Hertig.

Display and Bower-building in Bower-birds

AN investigation was carried out on the fairly typical bower-bird, *Ptilinorhynchus violaceus*, during 1939–41 in the Zoology Department of the University of Sydney and in rain-forests of eastern Australia. A full report of the investigation is at present in the Fisher Library in the University. The War having interfered with publication, the general conclusions reached are summarized below.

(1) The annual cycle of display and bower-building is dependent on the gonads and is stimulated by the same environmental factors that initiate actual breeding in other birds of the locality. Increasing light may be the principal stimulus; food and temperature have nothing to do with it.

(2) The male has already selected, or has been selected by, his mate when he arrives at his bower-territory after leaving the off-season feeding-flock in July. Thus bowers and decorations have little to do with sexual selection, which may have taken place during the winter flocking. It seems that the primary function of display and its associated specializations (bower, colour, 'decorations', noise, etc.) is to stimulate male and female reproductive systems as a prelude to successful fertilization. It is probable that external stimuli from the bower, etc., pass through visual and auditory receptors to the central nervous system and thence through the anterior pituitary to the gonads. Gonadectomy inhibits bower-construction and display. (Attempts to remove the anterior pituitary ended fatally.)

(3) Display and decoration of the bower begin in July–August: it is not until September–October that nesting begins.

(4) In the selection of its coloured 'decorations' or playthings the male Ptilinorhynchus closely matches the colours, especially the conspicuous epigamic features, of the female. During male display the female takes little or no active part—she may be absent or impassively present. The male's colour choices (blue, lemon-yellow and grey-brown) may serve the function of exciting himself by their resemblance to female colours.

(5) Some male birds paint or plaster the inner walls of their bowers with fruit-pulp, macerated wood or charcoal and other substances. The habit of painting coincides with that of breeding and not that of display.

(6) At least one species of bower-bird (Ptilinorhynchus), probably a second (*Chlamydera cerviniventris*) and possibly a third orientate their bowers across the sun's path.

(7) When the female leaves the bower-territory in September–October, she alone begins nidification and incubation, often in a part of the forest distant from the bower. The male continues his display without an audience and with undiminished vigour. This continues almost without interruption until January, when the female and her young arrive at the bower and a communal display takes place. In a few weeks, or days, the bower is deserted or wrecked, and the family party joins one of the large gregarious feeding flocks which are moving noisily through the fruit-bearing trees of the forest. In these flocks, numbering from ten to a hundred, a minor form of display is constantly taking place. The family parties are broken up in the feeding flocks.

A Simple Technique for Photomicrography

DR. LEAK's article in NATURE of May 6 has interested me very much; it describes a procedure which I think I was responsible for 35 years ago when I was working at Santa Elena in Entre Rios, Argentina.

I had an early Leitz microscope, and was interested in Texas cattle fever, blackwater and other trypanosome diseases. I had a good Kodak camera, and I also had a very early Kodak 'Brownie' camera making pictures on roll film about 2¼ in. by 2¼ in.—price 5*s*.—without view-finder. This little camera was so small and easily balanced that I found it unnecessary to do more than set up the microscope with the optical axis vertical, focus the object as for ocular observation as accurately as might be, and simply place the camera on the eyepiece, which was large enough to hold it quite safely without any other support, centring the lens by judgment and opening the shutter as smoothly as I could. I used a Welsbach mantle gas burner for the illumination.

Most of the pictures I took at that time were equal to anything I have taken since, even with very much more elaborate and expensive equipment. Unfortunately, I have preserved no prints or films.

EFFECTS OF CARBON DIOXIDE ON THE HEART AND CIRCULATION

In his presidential address to the Physiology Section of the thirty-first Indian Science Congress held in January, Dr. S. N. Mathur discussed the physiological importance of carbon dioxide. Carbon dioxide has generally been regarded as a toxic waste product which the body seeks to eliminate as rapidly as possible, but it is now well recognized that it has certain beneficial actions as well. Originally a necessary evil, it has, in the course of evolution, so inextricably worked its way into the body machinery that it has come to be indispensable for certain physiological processes. The necessity of carbon dioxide for maintaining the *p*H of the blood and the activity of the respiratory centre is, of course, well known; its importance for the proper working of the cardio-vascular system is less well appreciated, and this field, in which Dr. Mathur has made important observations, may be worth a brief review.

The fundamental experiments have been made on anæsthetized cats and dogs. The carbon dioxide content of the blood was increased by inhalation of carbon dioxide and decreased by forced breathing (hyperventilation). The most striking effect is on the arterial blood pressure, increase of carbon dioxide causing a rise of pressure, decrease a fall. This effect is due to the direct action of carbon dioxide on the vasomotor centre, the normal 'tone' of which is dependent on the continual stimulus of carbon dioxide. In addition, carbon dioxide has a peripheral action on the capillaries causing dilatation, which tends to cause a fall of blood pressure; normally, however, the central effect predominates and the net result is a rise.

In anæsthetized animals, increase of carbon dioxide causes slowing of the heart (sometimes there is a transitory initial acceleration). The slowing is partly reflex from the rise of blood pressure, but is mainly due to the direct action of carbon dioxide on the cardio-inhibitory centre. Conversely, hyperventilation causes acceleration of the heart.

Increase of carbon dioxide causes a considerable increase in the stroke volume of the heart, so that, despite the reduced heart-rate, the total output per minute is increased. The increase in stroke volume is due to increased diastolic filling, and it was thought that this was simply due to the rise of venous pressure which usually occurs. Dr. Mathur has shown, however, that the increase in cardiac output can occur quite independently of the rise of venous pressure, and he believes that carbon dioxide has a direct action on the heart-muscle, increasing the diastolic relaxation of the ventricle. When the carbon dioxide is reduced by hyperventilation, the cardiac output falls owing to reduced diastolic relaxation of the ventricle. He emphasizes this beneficial action of carbon dioxide on the heart in promoting diastolic relaxation and so allowing greater filling, which, owing to the intrinsic properties of cardiac muscle, automatically gives rise to increased output. He believes, further, that this increased cardiac output is an important contributory factor to the rise of blood pressure.

Previous workers had usually reported a reduction of cardiac output following administration of carbon dioxide. Dr. Mathur found that the increase of output with carbon dioxide was only to be obtained during the first hour or two of the experiment, while the heart was 'fresh'; after several hours of anæsthesia, the heart became 'stale' and then carbon dioxide caused a reduction of output. This seems to explain the discrepancies in the reported results. It seems rather surprising that an increase of carbon dioxide above the normal level should actually improve the efficiency of the heart. The general outcome, however, is quite clear, that a normal level of carbon dioxide in the blood is necessary for the maintenance of normal vasomotor tone, normal heart-rate and normal diastolic relaxation of the heart; these must all be reckoned as beneficial effects.

The general interpretation of these cardio-vascular responses to an increase of carbon dioxide is that the circulation-rate is increased in order to hasten removal of carbon dioxide. The slowing of the heart is, therefore, somewhat surprising; an acceleration would seem more appropriate. Dr. Mathur regards the slowing as a protective device, enabling the heart to conserve its energy so that it can survive longer under asphyxial conditions. It remains to be seen, however, if the slowing is a general phenomenon; perhaps it only occurs under anæsthesia. In man, inhalation of carbon dioxide always causes acceleration. In the whole animal the problem is complicated by the fact that the increased respiratory movements cause changes in the venous return which reflexly affect the heart-rate and the output. It is very difficult to disentangle these effects from the direct effects of carbon dioxide, and the whole problem requires further analysis. O. A. TROWELL.

ECONOMIC EXPLOITATION OF EUROPE AND ITS CONSEQUENCES

The analysis of German economic policy for Europe which was issued by the Royal Institute of International Affairs in March 1941 under the title "Europe Under Hitler: In Prospect and Practice" has now been followed by a further study, "Occupied Europe: German Exploitation and its Post-war Consequences"*. The measure of the change in the situation during the three years may be seen in the structure of the two booklets. The first emphasized the two parts of German economic policy: a short-term plan for the duration of the War; and a long-term plan for the permanent organization of Europe. The first booklet discussed both, but while the first part of the new study examines Germany's domination over occupied Europe and the mobilization and exploitation of its resources up to the autumn of 1943, the implications of a permanent German 'New Order' are no longer considered. Instead, the second part dealing with the post-war period discusses some of the problems to be faced during and after liberation, and in a couple of dozen pages gives a lucid account of the implications of German domination and the conditions which any plans for rehabilitation and reconstruction must seek to meet.

The first part of the booklet points out that, whether by military or political measures, the Germans have bereft all the occupied countries of their freedom. All resources, both material and human, have been mobilized for the benefit of Germany and often transferred to Germany, while under the

* "Occupied Europe: German Exploitation and its Post-War Consequences. Pp. 75. (London: Royal Institute of International Affairs, 1943.) 1*s*. 6*d*

blockade and war conditions, even the neutral countries can only maintain their economic life by diverting a high proportion of their normal trade to Germany or to countries under her domination. Sweden, for example, is now entirely dependent for supplies of coal, and for many other commodities, on imports from Germany, and in return continues to export to the Reich high-grade iron ore and other materials urgently required for the German war economy. Continental Europe has been taking about two-thirds of Sweden's export trade, of which Germany receives some half. Again, Germany has been forced by events to concentrate more on short-term plans for the mobilization of resources for their immediate effect than on long-term policy for the 'New Order', and the factors which govern the economic policy for any territory are the current requirements of the German war machine and the need for the maintenance and security of the German home front.

The fundamental difficulty in Germany's war economy problems is a shortage of man-power. The social and industrial consequences of the German exploitation of the human and material resources of the occupied countries, and the resultant food situation, need only to be pondered to realize how grave are the implications for the post-war period. The pamphlet, however, also directs attention to the enormous demand for fuel and power created by Germany's war economy, together with the shortages resulting from the British blockade of overseas supplies of oil and also raw materials. The extensive development of substitute raw materials and the power requirements of industry, as well as the demands of transport and the armed forces, have placed a tremendous burden on available supplies of coal, wood and electricity. The manufacture of substitutes is estimated to demand a third of the total output of electricity in the Reich and about one-fifth of the output of coal. Moreover, while Germany has gained control of all the main sources of coal in Europe, she has apparently been unable appreciably to increase production. The whole transport system under the control of Germany is now suffering from severe strain, motor transport has had to be cut to the barest minimum, sabotage is an increasingly important element and the railways of occupied Europe are being taxed and drained to the limit regardless of ultimate or immediate deterioration.

Agricultural production is being adjusted to serve Germany's special needs, with compulsory delivery at stable prices and the control of harvesting, enforced by heavy penalties. The long-term policy has attempted to increase production in the low-yield areas with adjustment in Western countries in consequence of the shortage of feeding stuffs, which has involved a compulsory decrease in draught animals, cattle, pigs, and other livestock. This policy has not conduced to willing co-operation from farmers in the Scandinavian countries and the Netherlands, and many factors have operated against the policy of increasing the production of oil seeds in south-eastern Europe. Improved weather conditions in 1943 more than compensated for shortage of labour, fertilizers and equipment. The yields of crops increased and the position as regards vegetable oils improved. With regard to industrial raw materials, in spite of the opening of mines and exploitation of resources, the lack of certain raw materials is still a problem which must be intensified by the loss of the manganese resources at Nikopol and bombing policy in the west, with the destruction of molybdenum mines in Norway, for example. In the U.S.S.R. the withdrawal of practically all skilled labour by the Russians, and their 'scorched earth' policy, made it difficult for the Nazis to execute plans for rapid economic development, and apart from manganese the gain in raw materials appears to have been small.

The review of the mechanism of economic exploitation adopted by the Germans in accordance with their policy of organizing the maximum development of essentials in their own interests draws largely on the Inter-Allied Information Committee's report, "The Penetration of German Capital into Europe". It is, however, well that it should be widely realized that as the occupied areas are released from enslavement they will be faced not only with conditions of starvation, destitution and probably, in consequence, disease, far more widespread and acute than in 1918–19, but also, in consequence of this exploitation, with far-reaching disintegration and breakdown of their national economies. Unless the British and American peoples fully understand the position, they can scarcely be expected to make the sacrifices that will be involved in their own standard of living.

While it is difficult to forecast the dimension or order of the problem of relief and rehabilitation, the second part of this booklet at least gives a succinct account of the immediate needs which the United Nations Relief and Rehabilitation Administration and similar bodies will have to face, whether the release of occupied areas is gradual or the collapse of Germany sudden. Detailed planning of long-term reconstruction has as yet only reached the stage of initial discussion and investigation, though the pamphlet gives some indication of the factors that may determine it—the development of synthetic and substitute materials, of hydro-electric power and transport, agricultural policy and adjustments; but the provision of relief and rehabilitation will be, as Sir Frederick Leith-Ross has pointed out, the test of the capacity of the United Nations to rebuild a more prosperous world and to give freedom from want in their territories. The Royal Institute of International Affairs in this pamphlet has done something to make plain what this will involve in terms of the continuance in the immediate post-war period of the shortages and rationing, controls and restrictions of war-time.

THE NUCLEOLUS

THE nucleolus was first figured in 1781 as a spot in the centre of a round or oval body (the nucleus) in epithelial cells of the eel. Since then it has been described in the nuclei of almost every type of plant and animal cell. Many interpretations were offered of its nature and function. Perhaps the view most widely accepted until very recent years was that it acted as a focus for the elaboration of chromatin which passed from it to the chromosomes as they developed through the prophase. During the last decade the use of Feulgen's reaction for the staining of nuclei has given a new impetus to the study of the nucleolus. This stain showed that at no stage does the nucleolus contain chromatin. Feulgen's stain, together with other modern cytological methods, has made possible the tracing of nucleolar behaviour through all stages of the mitotic and meiotic cycles, and has led to entirely new interpretations of the

role of the nucleolus. Most of the recent work has been done on plant cells. Although it is essential that much more attention be given to the nucleoli of animal nuclei, sufficient has been accomplished to show that plant and animal nucleoli are similar in essentials.

Three important discoveries during this century have determined the trend of modern research on the nucleolus. In 1912 were first seen, in Galtonia, chromosomes with satellites to which the nucleolus was connected. In 1926, the discovery in meiosis of Lathyrus of the 'nucleolar body' established a definite connexion between the chromosomes and the nucleolus. This body was a globule within the nucleolus to which the 'continuous spireme' was attached in prophase. With the methods then in use chromatin thread and nucleolar body stained similarly. In 1934, it was found that a 'nucleolar organizer' existed at a fixed point on certain chromosomes of maize. It was not of necessity visible as a separate entity but the nucleolus always arose in telophase at this point.

It is now well established that nucleoli are produced from the chromosomes in the telophase of mitosis. Each nucleus contains at least one pair of nucleolar chromosomes and each of the pair produces a nucleolus. The nucleolar chromosomes are frequently the sex chromosomes. Each of the pair has attached to it, by a very fine thread, a satellite which may be exceedingly small or may be a globular body as wide as the chromosome. The nucleolar organizer is usually at the tip of the chromosome at the point of attachment of the satellite thread; but it may be placed farther back at a secondary constriction. Suitable technique shows the origin of the nucleolus to consist of two minute granules, one on each strand, which stain similarly to the chromosome sheath. They may be formed from the material of this sheath, for it disappears as the granules increase in size. Any two nucleoli which touch because of growth or due to chromosome movement within the nucleus merge together. By the following prophase all are usually fused into a single body to which all the nucleolar chromosomes for some time remain attached. They break away when the nuclear membrane breaks down in late prophase and the nucleolus passes into the cytoplasm and disappears. A previous decrease in size of the nucleolus suggests that it may contribute material to the sheaths of the newly differentiated chromosomes.

The presence of several nucleoli at telophase, all of which fuse into one body before prophase, has been frequently described, but only recently has it been realized that the number of nucleoli is constant within any one species and is probably of as great phylogenetic importance as the number of chromosomes. Diploids may have one or more pairs of nucleolar chromosomes, and primary and secondary polyploids show a corresponding increase in their numbers of nucleoli countable in early telophase.

So much data on the nucleolus has accumulated that, although he gives eight pages of references, in his monograph "Nucleoli and Related Nuclear Structures"*, Prof. R. Ruggles Gates is able to quote only the more important work. Much of the earlier research obviously needs amplification or repetition using more modern technique. Gates deals briefly with the historical aspects of the subject, and then ably summarizes and critically reviews the more important recent work. As well as discussing the nucleolar cycle in mitosis in the normal higher organism, he discusses and brings into line the nucleolar behaviour in some lower organisms, he tells of related structures induced by pathological conditions and also discusses nucleolar budding. He refers to variations in nucleolar size due to physiological and other causes and evaluates the work on the chemical composition of nucleoli, much of which is at present inconclusive. He examines the relationships of the nucleoli with the chromosomes, the satellites and satellite threads. Gates suggests that the nucleolus may be of genetic and developmental significance for, after being in intimate association with genic material, at metaphase a large part of it is dissolved into the cytoplasm. Finally, he stresses the phylogenetic importance of the numbers of nucleoli, asking that future reports of chromosome numbers should include a determination of the number of chromosomes with satellites or secondary constrictions and the number and sizes of the nucleoli in somatic telophase.

F. M. L. SHEFFIELD.

THE HYGIENE OF THE EIGHTH ARMY IN NORTH AFRICA

LIEUT.-COLONEL H. S. GEAR, of the South African Medical Corps, has described the hygiene aspects of the El Alamein victory won by the Eighth Army in North Africa (*Brit. Med. J.*, March 18, 1944). "The Germans," says Colonel Gear, "must regretfully realize that their neglect" of sanitation "contributed seriously" to their defeat. Some 40–50 per cent of the German and Italian front-line troops were suffering from dysentery and diarrhœa, while the Eighth Army, thanks to the efficient methods outlined by Colonel Gear, was "probably as fit mentally and physically as any army has ever been".

The supply of rations to such an army, and of purified water to the quantity, during the preparatory phases at any rate, of one gallon a day for every man, must have been tremendous problems in themselves. The battle ration was reorganized, but, when the advance began, the rapid movement and dispersal of units created serious problems of cooking and refuse disposal. Each vehicle adopted the practice of preparing its own meals, a practice which resulted in feeding out of tins, waste of rations and the scattering of food remains over large areas, with the resultant encouragement of the breeding of flies. Mobile cooking lorries were therefore instituted, which carried hot, properly cooked meals forward to fighting men. It was found that continuous training and propaganda were necessary to ensure that all units had good cooks, proper company cooking arrangements and a sense of cooking hygiene and sanitation.

The water supply is always a vitally important problem of war in what Colonel Gear modestly calls "warm climates", because so many water-borne diseases exist which can rapidly destroy the efficiency of any force. El Alamein was supplied by water pipes laid from Alexandria by British Army engineers. These carried purified water for fifty miles into the desert and to points within a few miles of the front line. This was truly a remarkable feat. But, when this supply was left behind, the captured water points, polluted by the enemy with oil, dead bodies and filth of all kinds, had to be made fit for

use. When these in their turn were left behind, water was carried in tins and captured enemy water-containers. Older men who experienced the chlorinated water of the War of 1914–18 will realize what lies behind the sober account of these vital matters given by Colonel Gear. They will also be interested to hear that the sun topee was abandoned without bad results. Perhaps they will remember the friends who visited their Mesopotamian messes and next day were dead from the sudden 'effects of heat'. They will be glad to hear that no cases of heat- or sun-stroke or of other direct effects of heat were reported in the Western Desert. Even the tanks did not require special air-conditioning devices to protect their occupants from the effects of heat. Sun-glasses were not a general issue to the troops and Colonel Gear argues that they may actually be harmful, because people who get used to them in the relatively non-glaring atmosphere of, say, Cairo, may suffer intensely when they go to the white sand areas of the Western Desert.

It is a well-deserved tribute that Colonel Gear pays to the hygiene officers and men of the Eighth Army. Their work was not dramatic. Its daily details involved matters to which many adopt an ostrich attitude; it was hard slogging against difficulties which can only be overcome by meticulous attention to detail and insistence on discipline. Apart from the maintenance of efficient sanitation among the British forces, the Hygiene Corps had to supervise the Bedouin and other peoples who fled to El Alamein and became such a sanitary danger behind the British lines that they had to be removed. They were faced, like their predecessors at Mosul and other places on the Tigris during 1914–18, with the task of cleaning up the gigantic heaps of refuse and filth left behind by the retreating enemy. But they had the advantage of wise direction and an efficient sanitary organization.

It is time that a just tribute be paid to these men, who guarded, by their unremitting care, the lives and health of the fighters who saved Egypt and India. Without them the British armies might have suffered the fate of the Germans and Italians. Like the Royal Army Service Corps, the Royal Army Ordnance Corps and all the other supply services, the Hygiene Corps provided an essential part of that basis of efficiency without which the best of fighting men cannot succeed. G. LAPAGE.

FOREST PRODUCTS

ATTENTION has been directed in NATURE from time to time to the value and possible changes in the form of utilization of timber which plywood, one of the processes of lamination, renders possible. In an address before the Royal Society of Arts entitled "Forest Products", delivered on November 2, 1943, Mr. W. A. Robertson, director of the Forest Products Research Laboratory, dealt with the results of research and the future possibilities (*J. Roy. Soc. Arts*, **92**, Jan. 21, 1944). Great Britain will have to depend for its supplies of soft woods on itself (a negligible factor for some years to come), the Continent of Europe and on Canada.

As regards the forests of the British Empire, with the exception of Canada and Newfoundland the bulk lie in the tropics or sub-tropics, starting in the west with British Honduras and Guiana, on to the Gold Coast and Nigeria, thence through Uganda, Kenya, Tanganyika across to India, Burma and Malaya, and one large forest block in the south of Australia. The total area of these tropical forests is very large. The present area accessible to exploitation is estimated at 330,000 sq. miles, which is less than the area of soft-wood forests in Canada (more than 550,000 sq. miles). The two types are not comparable. Whereas the softwood coniferous forests are mostly pure (that is, of one species only) or at most two or three, in the tropical forests hardwoods prevail; species occur of varying degrees of hardness from very soft to the hardness of iron, and thirty or more species may be mixed together in a forest. To date but a few species have been in demand in Great Britain, and only a slightly larger number by the inhabitants of the countries in which the forests exist. Difficulties of commercial extraction under such conditions can be appreciated, also the failure to develop new markets owing to the mistaken policy of past administrations in insisting that the habits of the population, whether harmful to the forests and countryside generally and to a progressive development of the people concerned, should not be interfered with.

So far as difficulties of extraction are concerned, Mr. Robertson points out that the change is coming and that the new methods of use should permit of a much larger utilization. The first stage, he points out, is the change in the introduction of lamination usually associated with the term 'plywood' though, he says, lamination means much more than this. He explains it as follows in popular terms: "By the application of lamination we give up having to rely on the properties of chunks of timber as nature has given it to us with many defects and difficulties, and by arranging the timber in layers we balance defects with clear timber, we set off the weakness of timber in one direction by its strength in another and reduce the dimensional changes, i.e., the shrinkage and swelling. Thus a beam of 6″ × 3″ made up of ½ inch thick laminations can be about twice as strong as the same section cut out of solid timber of the same quality and a sheet of 3-plywood is 1½ times as strong in shear as a board of the same thickness, while its shrinkage and expansion is only one-thirteenth of the plain wood across the grain".

The possible methods of utilization thus opened out will permit of the elimination in some cases, or the distribution in others, of inevitable defects, so that they shall not occur at places of maximum stress where their weakening effect would be most felt. It may be pointed out that the application of this contention is not universal, as the oak timbers in the roof of Westminster Hall and many churches and old barns in the south of England will prove. But it is beyond dispute that with the ever-increasing demand for timber products, the new methods will permit of the use of lower quality timber "in the lightly stressed parts of an assemblage and reserve the best quality for the highly stressed regions". Finally, it permits of the utilization of short lengths of timber, the most fruitful source of waste in the past. As Robertson says, it is no secret that lamination has allowed the survival of the wooden aircraft, for without it the spars of the necessary length would have been unprocurable. Finally, it is pointed out that between 1932 and 1937 the imports of plywood into Great Britain increased from roughly 5 million cubic feet a year to 13 million, and that several of the main producing countries had reached the limits of their home-grown resources; the importance of

this change in the use of wood is therefore self-evident. The more so, as has already been pointed out in NATURE, that it should enable secondary industries to be developed on the countryside in the Colonies.

Mr. Robertson also dealt briefly with the possibilities opening out in the chemical utilization of wood, in which considerable investigations have been carried out in America.

FORTHCOMING EVENTS

Monday, June 5

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 8 p.m.—Mr. J. A. Steers: "Coastal Preservation and Planning".

Wednesday, June 7

PHYSICAL SOCIETY (COLOUR GROUP) (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 4.30 p.m.—Dr. W. D. Wright: "The Munsell System: a Review of Recent Work carried out by a Sub-Committee of the Optical Society of America on the Spacing of the Munsell Colours".

Friday, June 9

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Harold Spencer Jones, F.R.S., and Mr. R. T. Cullen: "Preliminary Results of Tests of and Observations with the Reversible Transit Circle of the Royal Observatory, Greenwich"; Sir Arthur Eddington, F.R.S.: "The Recession-Constant of the Galaxies".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5 p.m.—Mr. Michael Graham: "Men and Science in the Sea Fisheries".

Saturday, June 10

INSTITUTE OF PHYSICS (ELECTRONICS GROUP) (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Discussion on "Some Aspects of High Vacuum Technique, viz., High Vacuum Gauges and Glass Manipulation" (to be opened by Dr. M. Pirani and Dr. B. P. Dudding).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

GRADUATE to take SCIENCE, TECHNICAL DRAWING and MATHEMATICS in the Newcastle Junior Technical School of Building Crafts—The Director of Education, City Education Office, Northumberland Road, Newcastle upon Tyne, 2 (June 8).

ASSISTANT MASTER qualified to teach PRACTICAL PLANE and SOLID GEOMETRY for Engineering and Building Courses in the Plymouth Junior Technical School for Boys—The Director of Education, Education Offices, Cobourg Street, Plymouth (June 8).

LECTURER (man or woman) IN GEOGRAPHY AND MATHEMATICS—The Principal, Dudley and Staffs. Technical College, Dudley (June 9).

ASSISTANT LECTURER (temporary) IN MATHEMATICS, and an ASSISTANT LECTURER (temporary) IN GEOGRAPHY—The Secretary, King's College, Strand, London, W.C.2 (June 9).

DEMONSTRATOR (man or woman) IN THE PHYSIOLOGY DEPARTMENT—The Warden and Secretary, London (Royal Free Hospital) School of Medicine for Women, 8 Hunter Street, Brunswick Square, London, W.C.1 (June 9).

ENGINEER AND MANAGER of the Manchester Waterworks Department—The Secretary, Waterworks Department, Town Hall, Manchester 2 (June 10).

INSPECTORS (temporary) by the Board of Education (1) MECHANICAL OR ELECTRICAL ENGINEERING (Reference No. C.2125A), (2) AERONAUTICAL ENGINEERING (Reference No. C.2124A)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting the appropriate Reference No.) (June 10).

TEACHERS (two, temporary) with qualifications in MATHEMATICS and PHYSICS for Service Training Courses (approximately Intermediate Science standard)—The Clerk to the Governors, South-West Essex Technical College and School of Art, Forest Road, Walthamstow, London, E.17 (June 10).

OFFICER WITH THE TECHNICAL DEVELOPMENT COMMITTEE of the Holland War Agricultural Executive Committee—The Principal and Executive Officer, Agricultural Institute, Kirton, Boston, Lincs. (June 10).

GRADUATE ASSISTANT IN ENGINEERING (full-time) at the Llanelly Mining and Technical Institute and Junior Technical School—The Director of Education, Education Department, County Hall, The Castle, Carmarthen (June 10).

ASSISTANT MASTER (Graduate or non-Graduate) with special qualifications in BUILDING SUBJECTS, MATHEMATICS and SCIENCE, at the Hinckley Technical College—The Director of Education, County Education Office, Grey Friars, Leicester (June 10).

LECTURERS to take the following subjects for Evening Classes up to Matriculation standard: ELEMENTARY MATHEMATICS, GEOGRAPHY, CHEMISTRY, PHYSICS, BIOLOGY, LOGIC—The Director of Education, The Polytechnic, Regent Street, London, W.1 (June 12).

SENIOR LECTURER IN BIOLOGY—The Clerk to the Governors, South East Essex Technical College and School of Art, Longbridge Road, Dagenham, Essex (June 12).

GRADUATE ASSISTANT FOR CHEMISTRY AND MATHEMATICS at the School of Building of the East Ham Technical College—The Secretary for Education, Education Office, Town Hall Annexe, Barking Road, East Ham, London, E 6 (June 12).

TEACHER (woman, full-time) OF HOUSEHOLD SCIENCE AND HYGIENE in the Domestic Sections of the Day Trade School and in Part-time Day Classes of the Cambridgeshire Technical School—The Education Secretary, Shire Hall, Cambridge (June 12).

LECTURER IN PSYCHOLOGY AND PRINCIPLES OF EDUCATION—The Principal, Gipsy Hill Training College, at Bankfield, Bingley, Yorks. (June 12).

DOCKYARD MANAGERS for service in the Sudan (must be fully trained Marine Engineers holding University engineering degrees, or A.M.I.Mech.E. or A.M.I.N.A.)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2148A) (June 14).

CHAIR OF NATURAL PHILOSOPHY, United College, St. Andrews—The Secretary, The University, St. Andrews (June 15).

ASSISTANT HYDROGRAPHIC SURVEYORS by the Kenya Government Public Works Department—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.904A) (June 17).

ENTOMOLOGISTS in the Medical Department of Uganda, Northern Rhodesia, and the Tanganyika Territory, for general entomological work, with special emphasis on the investigation of tsetse fly and mosquito problems in the field as well as in the laboratory—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.2421A) (June 17).

HEAD OF THE PHARMACY DEPARTMENT—The Registrar, Technical College, Sunderland (June 17).

INSTRUCTOR IN PRODUCTION ENGINEERING—The Registrar, Technical College, Sunderland (June 17).

LECTURER IN ENGINEERING in West Africa—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.836A) (June 21).

PHYSICIST for essential War work (work would include experience in various research departments of a North London firm specializing in optical instruments for scientific and industrial research and control)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. A.518XA) (June 21).

COMBUSTION AND RESEARCH ENGINEER by large organization, with headquarters at Glasgow—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2031XA) (July 1).

ASSISTANT LECTURER IN ENGINEERING—The Registrar, The University, Manchester 13 (July 1).

ASSISTANT MECHANICAL ENGINEER for the electrical branch of the Nigerian Government Public Works Department—The Secretary, Overseas Manpower Committee, Ministry of Labour and National Service, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. 1931).

TEACHER OF SCIENCE (particularly CHEMISTRY) AND MATHEMATICS, and a TEACHER OF MATHEMATICS AND ENGINEERING SUBJECTS, at the Slough Junior Technical and Commercial School—The Secretary for Education, County Offices, Aylesbury, Bucks.

LECTURER (man or woman, temporary) FOR PHARMACEUTICAL SUBJECTS to Ph.C. standard—The Principal, Birmingham Central Technical College, Suffolk Street, Birmingham 1.

LECTURER IN GEOGRAPHY—The Registrar, The University, Reading.

MATHEMATICAL MASTER OR MISTRESS—The Acting Headmaster, Perse School, Cambridge.

LECTURER IN GEOGRAPHY (Honours Degree and special interest in human side of Geography essential)—The Principal, Furzedown Training College, at 29 Corbett Road, Cathays Park, Cardiff.

LECTURER (full-time) IN MECHANICAL ENGINEERING, and a MASTER to teach SCIENCE and MATHEMATICS in the Junior Technical School for Boys—The Principal, Wimbledon Technical College, Gladstone Road, Wimbledon, London, S.W.19.

PROGRESS TO PARTNERSHIP IN COLONIAL DEVELOPMENT

THE value of the Middle East Supply Centre and its potentialities have recently been discussed in these columns, and the contribution which regionalism might make to the solution of colonial problems in the field of welfare and economics appears to be gaining wider appreciation. Nevertheless, there has recently been disturbing evidence of unilateralism, and absence of forethought or of desire to co-ordinate American policy with that of Great Britain in the area which the Centre covers. The essential point is well made in an article entitled "Caribbean Laboratory" by Mr. J. M. Jones in the February issue of the American periodical *Fortune*. Colonial Powers, Mr. Jones observes, must now accept the increasing and legitimate interest of other nations in the welfare of dependent peoples; Americans must learn that helping other nations is not merely a matter of spending money and giving self-government, but also involves achieving trust and respect, the imparting of cultural standards and traditions, and the patient and self-sacrificing work of colonial servants over a long period of years. That is the basis of collaboration and of constructive criticism. Mr. Jones's review of British colonial policy in the West Indies and of Anglo-American co-operation in the Caribbean leads him to welcome and foreshadow, first the gradual extension of responsibility for dependent areas from the single Power exercising administration to the international society represented by regional commissions; secondly, the bringing together of dependent peoples themselves in regions where a community of need or interests exists to help each other in the attack on common problems.

Already it is clear that only an organization on the lines of the Middle East Supply Centre offers any prospect of securing the regional co-operation which is essential for effective development in that area. Unilateral action tends to provoke political difficulties even when it possesses the resources to achieve its limited purpose. The *Fortune* article may therefore be welcomed as evidence of a responsible point of view in the United States, and that at least some support will be forthcoming for the use for post-war purposes of effective instruments shaped primarily to serve war-time ends. The oil conference which began in Washington on April 16 may also promote confidence. The seconding of Dr. B. A. Keen and Dr. E. B. Worthington as joint scientific advisers to the Middle East Supply Centre to undertake a survey of scientific problems of the Middle East, from Libya to Persia and from Syria to the Sudan, indicates the importance attached by the British Government to the Centre as well as to scientific work overseas. The appointments should at least rouse further interest among scientific workers in these regional developments, the potentialities of which are as yet not widely appreciated.

It should not be thought, however, that obstacles to such developments are to be found in the United

States alone. Lord Cranborne, it is true, in a statement in the House of Lords, has indicated that the British Government would welcome collaborative and consultative machinery to facilitate the solution of problems which transcend the boundaries of political units in appropriate areas. This statement, which may well be an indirect reply to General Smuts' explosive thoughts on the new world last November, to some extent discounts the reluctance of the Government to commit itself in statements regarding the future of the Middle East Supply Centre. Moreover, there is nothing in the *Fortune* article which is at issue with the principle firmly maintained by Lord Hailey in his lectures at Princeton University in February 1943, which have now been published under the title "The Future of the Colonial Peoples" (Oxford University Press. Issued under the auspices of the Royal Institute of International Affairs. 1943. 3*s*. 6*d*.), that administrative responsibility must be undivided. The willingness or eagerness of the Colonial Power exercising administrative responsibility to govern and develop its dependent territories in accordance with the outlook and spirit of the international community does not, and should not, mean divided administrative responsibility.

It is not only in the Caribbean and in the Middle East that British colonial policy during the War has earned the sympathy and co-operation of the United States. "Mass Education in African Society", issued by the Advisory Committee on Education in the Colonies early this year (see NATURE, May 20, p. 606), indicates an outlook which is an immeasurable advance on the views of even two or three decades ago. Recognizing that the most formidable obstacle to development in Africa is illiteracy, the report argues that the problem must be attacked by the means, and on the scale, adopted in the U.S.S.R., China and Turkey. The evils and injustices which have to be overcome in Africa demand leadership, co-operation and an informed and intelligent public spirit. Co-operation, the active participation of Africans in the administration of their own country and the execution of great schemes of social reform are impossible if the community remains illiterate.

Education and social welfare must go hand in hand; and as Turkey has combined mass education with the organization of rural industries, so we may use it to meet the need, which Lord Hailey has emphasized, for greater specialization in African rural economy. By the measures indicated in the report, including the wide extension of schooling for children, with the goal of universal school within a measurable time, the spread of literacy among adults, together with the development of literature and libraries, the planning of mass education within the community as a movement of the community itself, involving the active support of the local community from the start, and the effective co-ordination of welfare plans and mass education plans so that they form a comprehensive and balanced whole, the report believes that proposals could be advanced for eliminating illiteracy within the next two or three decades.

With the details of the task ahead so ably delineated in the annexure to this report we are not concerned here, but the spirit and outlook of the whole document should compel tribute from even the severest critics of British Colonial policy. The note of urgency is rightly struck, for the next stage of partnership with the Colonial peoples cannot follow that of trusteeship unless and until those peoples are given every opportunity of equipping themselves to take their full place in the modern world. Moreover, this may well demand as generous provision of finance as schemes already under consideration for welfare and development. If mass education and welfare plans are in fact to be comprehensive, balanced and co-ordinated, there must be full understanding on the part of the citizens of Great Britain; for the responsibility of finding the necessary financial assistance will fall on them.

The case so ably argued in this report deserves to be made known as widely as possible, and it is the more important that public opinion in Great Britain should awake to the opportunity. The French Committee of National Liberation is considering a number of recommendations on French Colonial problems coming from a conference held at Brazzaville. These proposals also would handle public health and education in a large and generous spirit. They call, for example, for mass treatment of malaria and more preventive measures. A central school for medicine with a well-organized mobile service would demand an addition of 700 French and 1,800 African medical men.

Nor is it only in such fields as these that friendly emulation should arouse a wider and deeper public interest in Great Britain in Colonial affairs. When we are seeking with Lord Hailey to transform our relationship to the dependencies from that of trusteeship to that of partnership, it must be recognized that there are parts of the Empire where, in spite of specific pledges, the term trusteeship can scarcely be used to describe the spirit of our policy. Of these Kenya is a striking example, and uneasiness, not to say dissatisfaction, has repeatedly been expressed in both Houses of Parliament on this question. It is not too much to say that in Kenya the disparity in the treatment of the rights of the settlers and the rights of the indigenous population has become a matter of grave concern. That is attested by the studies in Lord Hailey's "African Survey" and by Sir Alan Pim's report on the financial position of Kenya quite as fully as in the less dispassionate publication of the Fabian Society, "Kenya: White Man's Country?" (Research Series No. 78). The Colonial Office is studying plans for remedying this neglect, which it is understood would provide for expenditure under the Colonial Development and Welfare Act on such objects as housing for Africans and the improvement of hospital and school accommodation. The Fabian Society paper welcomes such measures, but urges improvement both in the labour legislation and administration of the Colony—matters on which the recent International Labour Conference may be expected to have some beneficial effect.

There is substantial support for the view that white settlement in Kenya should never have been encouraged; but the termination of existing white settlement is rightly dismissed by the Fabian Society

report as not practical politics. On the other hand, the maintenance or extension, by fresh settlement, of the present privileged position of the European settlers is firmly opposed, and a programme for the political and economic advance of the population of Kenya as a whole is advocated as the most reasonable policy. This will involve various development schemes, as well as attention to the whole question of industrialization and the provision of transport, political representation of Africans and the abolition of all discrimination in favour of non-Africans regarding land occupation and tenure, backed up by vigorous attention to soil conservation, agricultural improvement and the like.

This report to the Fabian Colonial Bureau is a reminder that it will not always be possible to avoid political issues in dealing with Colonial problems. Much can be done, however, to make the political difficulties less acute by appropriate action in technical fields. Therein lies, in fact, one of the greatest hopes of a real contribution from such regional experiments as the Middle East Supply Centre to the solution of particular and dangerous political problems. The recent conferences organized by the Middle East Supply Centre, particularly the Agricultural Conference in Cairo, have shown, for example, that Jews and Arabs can come together to discuss schemes of regional development. Joint plans for raising the standard of living of Jew and Arab alike might go far to eliminate distrust and friction, while war-time experiments in the production of chemicals, plastics and rubber from industrial crops may stimulate the growth of a new technical and professional class in each community, with interests in common. This should still further assist participation in regional development schemes and provide wider possibilities of economic and political co-operation.

What is required is that the opportunities which are opened up for statesmanship should be realized and grasped. In Palestine, for example, there are possibilities of dealing with the difficult racial problem on wider lines in association with a Syrian Federation and with regional economic development in the Middle East. The West Indies Conference which opened at Barbados on March 13, when for the first time representatives of the Caribbean possessions of Britain and the United States met to discuss their common problems and work out a co-operative programme of action, has similarly indicated possibilities of Anglo-American co-operation which, if used with imagination and wisdom, may profoundly influence future world organization. Again, the present position affords us a great opportunity of putting Kenya on a sounder basis, both by large social reform and also by increasing African representation on governing and administrative bodies. There is much to be said for sending to East Africa a commission to do there what the Stockdale Commission did in the West Indies.

Whether or not such a measure be adopted, a report issued for consideration at the International Labour Conference entitled "Minimum Standards of Social Policy in Dependent Territories" will assuredly enforce reconsideration of British policy and administration in Kenya and elsewhere. No one document has put better than this report in its opening chapter the implications and possibilities of recent regional developments, and shown how successive steps such as the establishment of the Anglo-American Caribbean Commission, the Middle East Supply Centre and more recently the Agreement of January 21, 1944, between the Governments of Australia and New Zealand, envisaging the establishment of a South Seas Regional Commission, make one pattern.

The chief strands in this pattern are becoming clearer. They include a heightened conception of responsibility and an increased tempo in the development of self-government, closer relations between the dependencies and other interests in the different regions, and growing recognition that a main aim of policy should be the establishment of freedom from want; increasing co-ordination of economic and social programmes; a wider conception of social policy to include educational, public health and labour reforms; the establishment of new tropical industries and diversification of tropical agricultural production. The remoteness of tropical regions may well largely disappear through the development of air transport, but it is clear already that, apart from the world interest in security and welfare, these matters affect more than the Colonial Powers directly responsible for the administration of the separate territories.

It seems that, making allowances for local exceptions, the general economic foundations of social progress in dependent territories will be the development of the existing primary industries, supplemented by secondary industries concerned largely with processing primary products and providing elementary needs. Peasant development involves special difficulties, such as land tenure, where the spirit in which policy is administered is important. Again, there is the disputed question of compulsion for educational purposes or in the general interest of the country, and thirdly, the general problem of increasing the welfare of the peasant cultivator, not only by improving his methods but also by organizing the supplementary economic activities which he is not able to provide for himself.

Once again in this report we find the importance of education is stressed, particularly with reference to the evolution of self-reliance in social policy, the development of an individual and communal sense of informed responsibility, and of effective organs of consultation and collaboration. For the latter purpose the establishment of boards to deal with the co-ordination of social policy is suggested, and as a feature of regional technical collaboration the use of regional labour conferences. The main proposal of the report is that the appropriate authorities should examine the advisability of accepting certain fundamental principles of social policy in dependent territories and of providing for the extension and development of international minimum standards to such territories. A draft of such standards is included for submission by international agreement to the authorities concerned with a view to their application to dependent territories. These standards might also

serve as the principles subject to which the financing of developments in under-developed territories might operate.

In the territories where the present Colonial Powers retain direct control over labour and social policy, the fundamental principles formulated in this report should serve without difficulty as a basis of policy. If they are to apply to territories with wide and growing powers of self-government, the association of the immediate governments of those territories and their organized employers and workers will be required. Every effort must indeed be made to obtain the effective collaboration of peoples now dependent, in the amplification and execution of all measures on which their progress and well-being depend. That is a main purpose of the mass education programme, as it is part of the technique for executing that programme. Besides this, a large amount of technical and indeed scientific collaboration will be involved, and it behoves all whose services may be required in such duties to do their utmost to take the problems of development into an atmosphere of dispassionate inquiry and disinterested service. In so doing they best promote the participation of the American people with us and other trustees of Colonial peoples in the patient but expensive work of establishing the adequate basis in economics and education which is essential before politically immature peoples can stand alone. The cool critical spirit of scientific inquiry is an indispensable factor in the collaboration by which alone we can realize the immense possibilities inherent in regional developments, and build a new Colonial order in which freedom from want and from fear are assured to all without distinction of race.

VESALIANA

A Bio-Bibliography of Andreas Vesalius

By Harvey Cushing. (Publication No. 6, Historical Library, Yale University Library.) Pp. xxxviii+230 +86 plates. (New York: Schuman's, 1943.) 15 dollars.

ONE of the most remarkable developments of exact learning in recent years is the growth of an interest in the history of medicine and science which has shot up in the United States of America. It started almost from nothing, and with bibliographical resources wholly inadequate for detailed and accurate studies. The two Americans who stand out before all others in this movement are William Osler and Harvey Cushing—the former, it is true, of Canadian birth, but none the less an adopted and loyal son of the United States. Both must have been born with the love of books in the blood, and, having achieved eminent success in an opulent profession, they were able to impart a new and sustained impetus to the steady flow from Europe to America of the rarest and most expensive books in medicine and science.

Both Osler and Cushing were gifted with an impelling and charming personality, and succeeded almost without effort in communicating to others their own enthusiasm for the old masters. Like Prince Florizel of Bohemia, they gained the affection of all by the seduction of their manner and by a well-considered generosity. When Osler found himself in possession of six exemplars of the first edition of the "Fabrica", besides those already in his library, he offered copies to two institutions which as it happened possessed much better ones *presented by himself*! To those who knew Cushing only in his mature years, it comes as a shock to learn of a time when there were "cobwebs in the purse", and when a new purchase had to be smuggled into the house by the back door. But in later years he never considered the cost when there was a prospect of closing a vital gap in the library, and if sometimes he was inveigled into paying £50 for a book which should have cost him 50*s*., he at all events got what he wanted. He was, however, by no means the only American intent on acquiring the classics of medicine and science. There were many other costly private libraries in the making, and, as they grew, so the work of American historical scholars reached a degree of excellence which it would be presumptuous to praise. In one respect, however, these activities are by no means grateful to their European brethren, since America is clearly answerable for the astronomical prices which booksellers are now demanding, and presumably getting, for the older literature. For example, in my younger days I paid 50*s*. for an excellent copy of the first folio edition of the Parisian Memoires, but to-day the same bookseller is asking £75 for it, and the first edition of Harvey on the circulation has progressed from 4*s*. 6*d*. to £800!

The methods adopted by Osler and Cushing in building up their famous libraries were similar and effective. The books were personally hunted down in the collections and bookshops of Europe, the booksellers of which quickly discovered what America needed and made it their business to supply it. As Osler remarked on one of these forays: "I have bagged two 1543 Fabricas. 'Tis not a work to be left on the shelves of a bookseller. . . . We cannot have too many copies in America." The Surgeon-General's Library at Washington is the most complete and best catalogued collection of books of its kind in the world, and if we add to it the numerous private and public scientific libraries, it will be evident that the American student of the history of medicine and science is, from a bibliographical point of view, in an exceedingly strong position. For example, the stately new library of Yale University now houses collections of the earlier literature of the highest importance and value.

As we learn from Prof. Fulton, Cushing spent the last year of his life in preparing the present work for the press. For more than forty years he had been interested in Vesalius, and for the last twenty he had been collecting material for his book, the writing of which was still claiming his unremitting attention until within a few days of his death. The introduction and first five chapters had been completed, two others were planned, but the last three were untouched. "Had he lived a few months longer, he would, no doubt, have finished the work to his own satisfaction." These finishing touches, however, have been faithfully supplied by Prof. J. F. Fulton, Dr. W. W. Francis and Dr. A. Castiglioni. In the completed work the introductory matter includes Cushing's delightful personal "Apologia", a short sketch of the time and circumstances which led to the composition of Vesalius's works, the relations between Vesalius and his illustrator Calcar, and Cardan's horoscope of Vesalius. Chapter 1 deals with

Vesalius's degree thesis—"The Paraphrase of the Ninth Book of Rhazes"; Chapter 2 with the "Tabulæ Sex"; Chapter 3 with Vesalius's edition of Guenther's "Institutiones Anatomicæ"; Chapter 4 with the venesection epistle; Chapter 5 with Vesalius's contribution to the "Opera Galeni"; Chapter 6 with the "Fabrica" and its sequelæ; Chapter 7 with the China-root epistle and the aftermath of the "Fabrica"; Chapter 8 with Vesalius as a consulting physician; and Chapter 9 with the Fallopius-Vesalius controversy. Chapter 10 is a valuable bibliography of Vesaliana, which is followed by an index of recorded copies, a chronology of editions, and an index of names.

Cushing's conception of what a bibliography should be was emphatically the right one. To him a book like the "Fabrica" of Vesalius was a living influence, and to dismiss it in arid records of dates and collations did violence to his artistic sense and penetrating imagination. Consequently he discusses the details and circumstances of its printing and illustration, the methods of publication and the wiles of publishers, the unblushing operations of the plagiarists, and above all the environment in which the book was conceived, and its influence on contemporary and posterior thought. He even tells us how, when, and at what cost he acquired his own copies. All this results in the production, not of a reference book which is promptly relegated to the shelves, but of a scholarly human treatise which can be read.

The most valuable sections of the work are the chapters on the few and rare fugitive sheets known as the "Tabulæ Sex", on the "Fabrica", and on the more popular "Epitome". It is doubtful whether any private or public library rivals Cushing's collection of Vesaliana, and he could hence pursue his studies at home with but occasional extraneous intervals. The bibliographical details which are given will be indispensable to students of Vesalius and librarians generally, not to mention the specialist booksellers. Cushing bequeathed his books to his old University, and Prof. Fulton has now added his own collection, so that Yale can offer almost unique facilities to those who wish to undertake historical researches in America. In this connexion two observations and an anecdote which are related by Cushing in this work may be recalled. History, he remarks, "has proved a solace for many of us in our later years"; and again, "the Fabrica has probably been more admired and less read than any publication of equal significance in the history of science". Now the anecdote: in 1914 Cushing and Streeter decided to celebrate the quatercentenary of the birth of Vesalius by an exhibit at the spring meeting of the American Medical Association. "For this purpose," he says, "we were allotted a booth and had a small pamphlet printed with a description of the books we had selected for display. It aroused little if any interest. We had arranged to alternate as showmen, Streeter in the morning hours, I in the afternoon. We met at lunch after the first morning and on my enquiring 'How did it go?' he replied, 'Well, only one old codger stopped long enough to read the sign VESALIAN EXHIBIT and said, 'Got any samples?' Streeter asked 'Samples of what?' He pointed to the sign and said, 'Samples of 'Vaseline', of course'. Sadder and wiser we returned to Boston with our 'samples' at the end of the week."

It only remains to add that this memorial to a great European is also a memorial to a distinguished and beloved American. It has been beautifully produced by the publisher, Henry Schuman.

F. J. COLE.

AMERICA A CENTURY AGO

Mirror for Americans

Likeness of the Eastern Seaboard, 1810. By Prof. Ralph H. Brown. (American Geographical Society Special Publication No. 27.) Pp. xxxii+312. (New York: American Geographical Society, 1943.)

THIS work is, in its author's words, "intended as a short cut to an understanding of American geography in 1810". It is compiled from a great variety of sources and is written in the style of the period it portrays. Its author is to be warmly congratulated on his skill and his imagination: the former has produced an admirable account of the historical geography of the eastern seaboard in or about the year 1810; the latter has invented a character, Thomas Pownall Keystone, who tells the story "which he might have written and illustrated" through the medium of Prof. Ralph H. Brown.

The work covers every field of activity and enables us to see, in their early stages, some of the fundamental questions that have been presented to the Republic. Was the climate changing and had it changed? Some, relying on earlier accounts of the country, said it had. Others, from scientific examination, argued that increasing cultivation led to less severe winters but "more inconstant, variable, and unsteady weather". One scientific worker maintained there had been no change. In a note Prof. Brown remarks: "the question of climatic change . . . pervades the entire literature of this period".

What population could this new country support? Some took the gloomy view, and put the limit at ten millions. Others optimistically predicted a population of eighty millions in 1876—a figure of thirty millions more than was attained. One writer foretold a population of 860 millions in 1946! These speculations were natural in view of the rapid growth of population at the beginning of the last century, largely through a great excess of births over deaths. But already the problems of this population were showing themselves. The Negroes were increasing both relatively and through the continued import of slaves and had already become a 'problem' in Virginia, where in parts there were "more blacks and even more slaves than free white persons". One Virginian contrasted this evil "which is now so thoroughly incorporated" with the happy state of New England, where the problem scarcely existed.

Much of this book is taken up with detailed accounts of means of communication, occupations, trade and industry and with regional accounts of various parts of the seaboard. Each chapter has its particular interest, too detailed for quotation in a short notice; such as coastal erosion at Cape Cod; the beginnings of the textile industry in the northern States; the spread of settlement westward in New York State; the commercial interest in Florida, then "little better than a wilderness" and still a Spanish possession; the industrial future of Pennsylvania, delayed only by "the difficulties of transportation and the prejudices of the people"; and the planning of the lay-out of some of the cities of the east. Dominating all is the story of the subjugation of a country by human enterprise shown in a great variety of ways. The continent was one of possibility: the population of the eastern seaboard was exploring and exploiting the immediate possibilities and, when tempted by land speculators or roused by curiosity, or even impelled by its growing numbers, was pressing westward to sample the wealth of an almost unknown

interior. This last region was, however, largely a blank on the maps in the mythical library of "Thomas P. Keystone, Esq." and is not discussed in this book.

This fascinating story is illustrated by a number of contemporary maps, plans and views, and Prof. Brown has added a select bibliography and many useful notes. The book is issued by the American Geographical Society and more than maintains the high standard of its publications.

J. N. L. BAKER.

PRACTICAL PHYSICAL CHEMISTRY

Physico-Chemical Methods

By Prof. Joseph Reilly and Prof. William Norman Rae. Fourth edition, revised. Vol. 1. Pp. ix+610. Vol. 2. Pp. vii+586. (London: Methuen and Co., Ltd., 1943.) 2 vols., 84*s*. net.

THE fact that another edition of "Reilly and Rae" has been called for after a lapse of only three years —abnormal years from the academic point of view—is adequate testimony to the usefulness of this comprehensive work on practical physical chemistry. A complete revision would have been impossible, but the authors have managed to prune out a good deal of material more suited to an introductory text than to an advanced treatise. Simultaneously they have introduced new matter by adding the necessary pages under a decimal system of pagination; the original pagination thereby being preserved. It is to be hoped that this war-time measure will disappear when conditions permit. The whole work tends to grow, for another volume is promised, dealing particularly with gas analysis, microanalysis and related topics.

Space prevents mention of all the additional matter, but the authors have lost no opportunity of introducing methods of recent origin; for example, in volume 1 Emmett's method for the determination of the specific surface of sub-microscopic particles, high-speed stirring equipment, data on the properties of laboratory glasses, the latest apparatus for hydrogenation and new photographic techniques and sensitive materials. Previous gaps have been filled by the inclusion of new sections on the graphical representation of three-component systems, thermocouples and thermopiles, and on the determination of the specific heats of liquids. Similarly, in volume 2 there are innumerable additions. Gas analysis is an ever-expanding technique, while distillation naturally assumes an important place with appropriate additions to an already complete chapter. There is an especially interesting and valuable section on microdiffusion in liquid systems. Brief mention is made of the technique of growing large crystals and of some of the applications. A few pages are devoted to the air-driven ultracentrifuge, but the oil-driven type is only mentioned in passing. Although some small additions are made to the chapter on adsorption, the necessary expanded treatment is reserved for the third volume. A similar arrangement is made for the electron microscope. The glass electrode and the measurement of the dielectric properties of solids both come in for some revision. There is only a small point of criticism. A few of the diagrams could be better drawn in order to be worthy of the work as a whole.

In a comprehensive book of this character, it is presumed that every topic having a bearing on physical chemistry must be described. To follow such a presumption leads to difficulties, for in some directions the techniques have become so highly specialized as to be unsuitable for inclusion in this kind of manual. They require to be treated by a specialist in a separate monograph; for example, the ultracentrifuge, electron microscope, infra-red spectroscopy, X-ray crystal analysis and radioactive technique come into this category. While the omission of these topics might leave the impression of incompleteness, no physical chemist would reasonably object, since standard works on these subjects exist. The real function of the volumes under review is to bring together all the multiplicity of techniques, methods and appliances used in modern physical chemistry, but often unknown to, or undiscovered by, those practising the subject. "Reilly and Rae" already fulfils this function, and it is hoped will continue to do so in an even greater measure with the promised appearance of a third volume to complete the work.

H. W. MELVILLE.

THE EXTRUSION OF METALS

The Extrusion of Metals

By Claude E. Pearson. Pp. viii+205+37 plates. (London: Chapman and Hall, Ltd., 1944.) 18*s*. net.

IT is not a little surprising that an important industrial process, well over a hundred years old, should have had to wait until now for an author. Particularly is this the case where the process is one which has shown such marked advances as has extrusion during the past twenty or thirty years. Starting as a means of forming lead pipes, it is now a method of working metals which is of first-rate importance, and its potentialities, so far from being exhausted, may result in its serious incursion in the comparatively near future from the realm of nonferrous metallurgy into that of the steels.

In this little volume the author gives a general survey of the whole field, theoretical as well as practical. The treatment is well balanced, and the information, collected from many sources, is clearly and impartially discussed. It is, however, more or less of an introduction to the study of extrusion, and to those already familiar with the process and the materials to which it is applicable, there will not be much which is unknown.

How much now remains to be investigated is shown by the wide gaps which still exist in our knowledge of the nature of the flow of the metal and the stresses required to effect it. The shape and contour of the die, for example, a matter to which the wire-drawer has for long devoted most careful consideration, receives only the most general treatment, although it must have a profound influence upon the ease with which the process is carried out. In this connexion, too, it may be pointed out that equation (8) on p. 125, in which the die angle is introduced, is similar to one proposed for wire-drawing, where its predictions are by no means entirely in accord with experimental results.

As a general introduction to its subject, this book is good; in its implications of the large field of work still demanding attention, it will be of real service to the research worker, but one puts it down with the impression that a process of such immediate importance and with such immense possibilities of expansion deserves a more comprehensive and detailed treatment than it has yet received.

F. C. THOMPSON.

Elementary Morphology and Physiology for Medical Students

A Guide for the First Year and a Stepping-stone to the Second. By Dr. J. H. Woodger. Third edition. Pp. xvi+522. (London: Oxford University Press, 1943.) 15*s*. net.

FIRST published in 1924 this text-book has now passed into its third edition, a fact which testifies to its usefulness. The book has been thoroughly revised and an additional chapter on insects, with *Periplaneta americana* chosen as the type, has been included. The revision has been well carried out on the whole, and this has involved some of the illustrations as well as the text, but it is a pity that the account of mitosis was not more completely rewritten and not simply left as the traditional account with a note that it requires modification in the light of recent observations.

The book differs from many of the text-books for medical students in that it assumes the use of other practical texts for the acquisition of factual knowledge; the author rightly observes that no book can replace personal observation. This does not imply that the treatment of morphological facts is omitted; they are indeed well treated, but the emphasis laid upon them is not so marked, and more attention is paid to what, for the want of a better term, may be called theoretical aspects. In order to do this satisfactorily the author has found it necessary to go outside the actual types laid down in the examination syllabus; for example, the interesting chapter on the primitive Amphibia and the reptiles, to give an idea of the history of the origin of the mammals. The result is that the reader will obtain a rather wider outlook on matters zoological. Perhaps one of the most important sections from this point of view is the chapter on theoretical biology and the methods of science, and the student would be well advised to read this carefully and consider its applications to all his work. The text and illustrations are well done, and the volume is deserving of commendation.

Ultra-fine Structure of Coals and Coke

Proceedings of a Conference held at the Royal Institution, London, June 24th and 25th, 1943, by the British Coal Utilisation Research Association. Pp. 366. (London: H. K. Lewis and Co., Ltd., 1944.) 25*s*. net.

A CONFERENCE on the structure of coal was held in London on June 24–25, 1943, and the present volume is an account of its proceedings. It comprises a set of scientific papers together with discussions of their contents and forms a valuable book of reference for those who study coals and cokes.

It can scarcely, however, be regarded as a book of reference for facts, since the general impression given is of the lack of knowledge about the subject. This is evidenced by the number of theories put forward by the various investigators and by the, at times, rather impatient tone of the discussion. While this state of mind is probably inevitable at the beginning of a new subject—as the scientific study of coal undoubtedly is—one feels that more receptive states of mind would be a happier augury for the future.

On the other hand, the promoters of research are to be congratulated on their breadth of vision in applying new research tools. These include X-ray diffraction, electron microscopy, the measurement of the heat evolved in wetting by certain organic liquids, the measurement of magnetic anisotropy and infra-red spectroscopy. While none of the methods employed has given a complete answer to any of the problems raised, the integration of the results they are producing is bound to be informative. If, therefore, the present volume is regarded as a 'clearing house' for ideas it will have served its purpose. It would be interesting to see what a corresponding volume would contain if it were produced in, say, twenty years time. H. L.

The Biotic Provinces of North America

By Lee R. Dice. Pp. viii+78. (Ann Arbor, Mich.: University of Michigan Press, 1943.) 1·75 dollars.

BY recognizing a series of floras associated with definite areas in North America in 1830, C. Pickering laid the foundation of the biogeography of that area. This was added to in 1843 by R. B. Hinds but established on more or less modern lines in 1859 by J. G. Cooper, who recognized a series of regions to which geographical names were applied. Since that time a great deal of attention has been paid to this topic both in the broad sense of dividing North America as a whole and in the more detailed analysis of limited areas from the points of view of the distribution of plants or animals or the effects of climate.

Lee R. Dice has made the most recent contribution to this subject in the book under review, in which twenty-nine biotic provinces are recognized and a map showing them is provided. By biotic province the author means a continuous area of reasonable size that is characterized by one or more ecological associations that differ sufficiently from those of adjacent provinces to constitute an entity. In the absence of some striking geographical barrier it is obvious that one province may pass over into the next and so the position of the actual dividing line may be a matter of convenience or opinion. In view of their different natures, plants can be utilized more readily for such a purpose than the more mobile or even migratory animals. The author, whose contributions to the zoogeography of vertebrates are well known, has considered fully the previous work and so far as possible utilized in his terminology names that have been applied already, with the necessary redefinitions. It would be unfair to leave the impression that the book is merely a résumé of the work of others. He has himself studied the ecological associations and conditions in nearly all the provinces, and it is in his critical evaluation of these factors that the main value of this well-produced volume lies.

The American Land

Its History and its Uses. By William R. Van Dersal. Pp. xvi+215+65 plates. (London, New York and Toronto: Oxford University Press, 1943.) 21*s*. 6*d*. net.

IF a book can be classed as good when it fulfils a predefined object, then this book is good. The author has been fully impressed by the wealth and greatness of his own country, and in simple but logical diction has painted a canvas of distinction. Corn, wheat, barley, fruit, cotton, vegetables and subsidiaries are all there in detail, which is surprising, considering the simple terms used; and a series of excellent photographs makes for a well-balanced whole. As learning increases, so man's ability to absorb the whole of it decreases. The consequent era of specialization has created gaps in human knowledge which appear impossible of closure, and in a sense these gaps may be accounted a serious detriment. The real value of this book is as a stepping-stone across the break. D. CARPENTER.

HUMAN LIMITS IN FLIGHT*

By DR. BRYAN H. C. MATTHEWS, F.R.S.
R.A.F. Physiological Laboratory

A MODERN aircraft will climb in a few minutes to heights at which the air is so thin that it will no longer support life. It can turn and manœuvre so fast that the pilot may easily be rendered unconscious from the mechanical forces which it can impose on his body, and in an aircraft which is moving rapidly in three planes of space the pilot can be subjected to stresses beyond the limits which the human body can stand.

The adaptation of which the human body is capable to new surroundings and conditions can play a considerable part in fitting man to these new conditions; for example, airsickness which many suffer on first flying in rough air or doing aerobatics, in most people soon passes off and they become adapted to motions which at first perplex and incapacitate them; though a few never become completely adapted. But there are several stresses placed on man in aircraft that cannot be met by any unconscious adaptation, which require equipment specially designed to meet them. Some of the necessities are obvious, such as windscreens to protect the man from the enormous wind pressures at high speed and a heat supply from the engine and special clothing to keep him warm in the arctic cold of the stratosphere. His senses must be extended by a set of blind-flying instruments so that he may know his altitude and movement in space when in clouds or at night. He must learn to believe the instruments against his senses, for these are no longer a reliable guide when he may be moving at varying speeds in any direction—in fact, they will often be wrong. The human limit of visual range by day and especially by night is of paramount importance in flying.

But besides the stresses from wind pressure, cold, vibration and noise, the pilot's body must also be protected from other less obvious stresses, and here I propose dealing particularly with the two greatest stresses which an aircraft puts upon the pilot: those due to acceleration or rapid change of motion and those due to high flying in the rarefied air of the upper atmosphere.

In the last hundred years man has increased the speed at which he can travel more than tenfold, but there is no reason to suppose he is approaching any human limit in speed for, provided that he is protected from wind pressure by a closed cockpit and that the motion does not change rapidly in direction, there is no more mechanical stress on the pilot than if he were sitting on the ground.

If the human body is moving uniformly there is no force acting on it other than that due to gravity, recognized as weight. But when the motion changes in either magnitude or direction, large forces come into play; for example, while launching an aeroplane by catapult. During this linear acceleration, the pilot has the sensation of being driven backwards against his seat by forces equalling several times his own weight. This is seen in the retracting of the skin of his face, which bares the teeth like a snarling dog. In this case, the acceleration acts transversely on the body and lasts only a few seconds, and in this direction the pilot can easily withstand many times the acceleration of gravity provided his head and shoulders are well supported.

When a fast-moving aeroplane changes its direction and turns, aeroplane and pilot are both subjected to very large forces. The phenomenon known as blacking-out came into prominence in the Schneider Trophy races; pilots found that in turning at high speed their vision became blurred and that for a few seconds in the turn they frequently became blind. This is now a common event in aircraft and is well understood by fighter pilots.

When an aeroplane travels in a curved path in turning or pulling out of a dive, a large centrifugal force tends to force the aeroplane and pilot away from the centre of the circle. The magnitude of this force increases with the square of the speed and decreases as the radius increases. Subjectively, a pilot experiences a great increase in weight of all parts of his body as the centrifugal force tries to drive his body out through the bottom of the aeroplane. The magnitude of the acceleration acting on the pilot is expressed in terms of g, the force due to gravity normally acting on the body which causes it to have its normal weight. Thus in a turn producing $4g$ or four times the force of gravity, if the pilot's seat were fixed to a spring balance it would register four times his normal weight and the pilot and all parts of his body become extremely heavy. This is seen in the sagging of the soft part of the face which occurs in a tight turn (Figs. 1a and b). A turn at 300 miles per hour and 1,000 feet radius produces $6g$, and a pilot in effect weighs about half a ton and his blood virtually becomes as heavy as molten iron. The blood is normally being pumped to the pilot's head by his heart, but as its virtual weight increases, the heart has difficulty in maintaining the blood supply to the head. The brain and the eyes can only function for a few seconds without their normal blood supply, and loss of vision in blacking-out is due to failure of the circulation in the retina of the eye. If the acceleration is still greater, the whole blood supply of the brain fails and the pilot becomes unconscious.

Blacking-out is a warning that the blood pressure in the cerebral arteries is getting low. If the control column is eased forward, the aeroplane straightens out, the centrifugal force ceases and within a few seconds the circulation returns to normal. While this happens in the head the deficit of blood tends to gravitate to the legs, and the phenomenon can be regarded as the head losing blood to the feet.

This draining of the blood from the head takes time. The greater the acceleration the less the time that the pilot can retain his sight.

Many measures have been taken to reduce the effect of centrifugal force on the pilot; much may be done by posture and seating. If the pilot's attitude is crouched with his legs raised, the distance through which the heart has to raise the blood to his head can be reduced, and the loss of it to his feet is again less if the feet are high. Another method of lessening the effect of this force which may be mentioned is to place the pilot in the prone position. The heart and head are then nearly at the same height and a man in this position can withstand some $10g$, but this posture is a very fatiguing and inconvenient one for the control of an aircraft, though it is reminiscent of the very earliest aeroplanes in which the pilot frequently lay prone. The effect of posture on blacking-out is shown diagrammatically in Fig. 2.

The engineer has produced machines that are so strong and manœuvrable that they can subject the

* Friday evening discourse at the Royal Institution, delivered on June 11, 1943.

pilot to forces beyond his tolerance, and the useful limit in design for manœuvrability at high speed changes from being an engineering limit to being a human limit. It would be useless for the aircraft designer to produce an aeroplane so strong and manœuvrable that it could turn with a centrifugal acceleration of $20g$, because the pilot would not be conscious to control it under these conditions; the ability to out-turn the enemy has an important tactical advantage in 'dog-fighting', but to achieve this it is now necessary to look to the man rather than the machine. Fig. 3 illustrates how the human limit makes it impossible for a fast aeroplane to follow a slow one in a tight turn; both pilots are subjected to $5g$.

The most important stress, however, to which man is subjected in aircraft is that resulting from the thinness of the air at great altitudes.

The air pressure at ground-level is 14·7 lb./sq. in. (Fig. 4), it has fallen to one half at 18,000 ft. and to less than one fifth, about $2\frac{5}{8}$ lb./sq. in., at 40,000 ft. The effects of altitude on man are those resulting from the lowered atmospheric pressure.

The disabilities which a man suffers at lowered pressure first came into prominence on the surface of the earth as 'mountain sickness'. Later the term 'balloon sickness' was given to the troubles experienced in high balloon ascents at the beginning of the last century; long before aeroplanes had become practical flying machines, the problems of high altitudes had been encountered, because early balloon ascents carried the balloonists to heights at which the air would scarcely support life, and at that time their knowledge of how to overcome this was lacking.

It is necessary to emphasize the difference between rapid ascent from ground-level, as in an aeroplane, and slow ascent in climbing mountains. In the latter case, weeks are spent at 15–18,000 ft. to become acclimatized to the thin air. Great changes occur throughout the climber's bodily processes which enable him to live at altitudes which are fatal to a 'sea-level' man. Acclimatization is soon lost on return to ground-level, so it is not possible to make much use of this in flying.

Climbers have reached 28,000 ft. on Mount Everest, but in contrast to this the first serious high-altitude accident occurred in 1875 when Tissandier with two companions went up in the hydrogen balloon *Zenith*. The balloon ascended to about 26,000 ft. and the occupants became unconscious; although they carried bags of oxygen they failed to make use of them. They became conscious again when the balloon descended to 20,000 ft. but then threw out ballast and the balloon rapidly ascended to about 28,000 ft. All became unconscious, and when Tissandier regained consciousness the balloon was at about 19,000 ft., descending rapidly, but his two companions were dead. This accident focused a great deal of attention on the physiological problems of altitude, and to investigate these Paul Bert constructed a steel chamber from which the air could be removed by a pump to simulate altitude conditions at ground-level. Since then a great deal of research has been carried out in such decompression chambers, on mountains, and in aircraft, on the nature of altitude sickness and the ways of overcoming it.

Fig. 1*a*. Man during straight and level flight.

Fig. 1*b*. In a tight turn producing acceleration of $4\frac{1}{2}g$ 15 seconds later.

The R.A.F. Medical Service uses decompression chambers in which a man can be taken to a pressure equal to that at 30,000 ft. in less than a minute, and are capable of producing pressures down to a small fraction of a pound to the square inch.

For life, man needs food, water and air. He can live without food for weeks, without water for days,

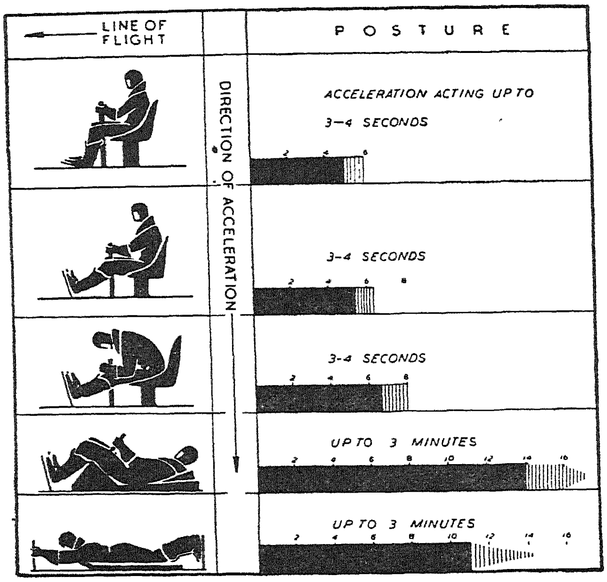

Fig. 2. EFFECT OF POSTURE ON THE TOLERANCE OF ACCELERATION. (DATA FROM RUFF.)

but without air he can survive only a few minutes.

At increasing altitudes, although the proportion of oxygen in the air remains one fifth, the density of the mixture becomes less, and a certain pressure of oxygen is essential for living cells to function normally. At an altitude of 42,000 ft., if the lungs are filled with air they contain less than one sixth of the normal quantity of oxygen, and this is insufficient to support life. Much of the Battle of Britain was carried out in an atmosphere in which a pilot unassisted with breathing apparatus would be dead in a few minutes. However, long before this height is reached, oxygen-lack makes its presence felt in the impaired intelligence and mental performance of the pilot. As oxygen-want comes on, judgment is lost, gross errors are made, intelligence fails, muscular control is lost and this may be followed by unconsciousness and death if the anoxia is severe. Moreover, oxygen-want is very insidious because the sufferer is often almost unaware of it. At 20,000 ft. a man without oxygen may do irrational things; oxygen-want resembles drunkenness both in its symptoms and in that the sufferer is confident that he is normal and much resents any suggestion to the contrary.

It would clearly be dangerous to send an aircraft up to 25,000 ft. unless it was ensured that the crew were protected from oxygen-want. Much research on the practical protection of flying personnel from the effects of altitude has been carried out by the R.A.F., particularly by the Medical Branch, which directs research in this very important side of the pilot's welfare. The importance of this is emphasized by the following true story of an incident which occurred over Germany. A pilot's breathing apparatus became disconnected, and the pilot thereupon told the crew that he was going to land. He put down his wheels and tried to land on a cloudbank at about 18,000 ft. He then told the crew over his intercommunication system that they were below ground-level and he was going to get out, whereupon the navigator, realizing what had happened, was in time to stop him climbing out of the machine, take over the controls and re-connect the pilot's breathing apparatus. It is easy to see that such an incident might not always have a happy ending. The effects of oxygen-want may often be extremely amusing, but clearly there is no place for such events in the dangerous and difficult work of high-altitude flying.

There are two ways in which altitude effects can be overcome. The first is to increase the amount of oxygen in the air which the pilot breathes by mixing oxygen from gas cylinders with it, thus giving the pilot a mixture rich in oxygen or even pure oxygen to breathe. In this way when the pressure is one quarter of an atmosphere at 33,000 ft., if his lungs are filled with pure oxygen he will not suffer from any symptoms of oxygen-lack. To this end the pilot always wears an oxygen mask, which also carries a microphone for his communication with the crew or ground.

The second alternative is to increase the amount of oxygen in the pilot's lungs by compressing the air in them. In an engine the loss of power from oxygen-lack is overcome by compressing the thin air with a supercharger; but it is not possible to supercharge the lungs so easily, as the pressures required would burst them. The pilot must therefore be completely surrounded by air at increased pressure. This can be done either with a pressure-suit something like a diving dress, or by sealing the cabin and making it strong enough to withstand a raised air pressure produced by a pump attached to the engine. The air around the pilot can then be kept at 14 lb./sq. in. and the atmosphere he breathes can be exactly like that at ground-level. However, it is clear that for military use such a pressure-cabin is very vulnerable, though for civil use it is the ideal method in high flying because the passenger is not inconvenienced by a mask on his face and need not be aware, by any change in the air pressure, that he has left the ground. Both alternatives are in use in civil airlines. The pressure-cabin has other advantages over the oxygen mask besides preventing lack of oxygen. At heights up to 36,000 ft. a man can avoid oxygen-lack by breathing pure oxygen, but above 44,000 ft., even breathing pure oxygen, he would become unconscious. Moreover, the vapour pressure of blood equals the atmospheric pressure at 63,000 ft., so if a man could reach this pressure his blood would boil and his lungs be filled with steam. At heights above 40,000 ft. it becomes necessary not only to breathe pure oxygen but also to increase the

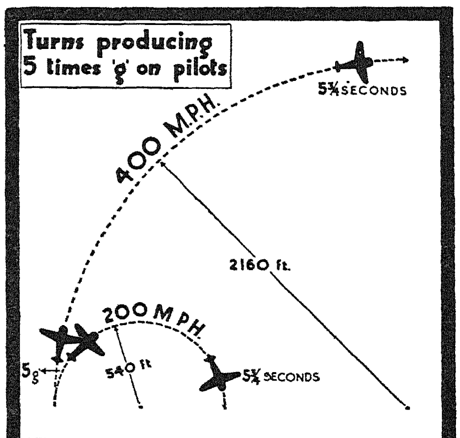

Fig. 3. HOW HUMAN TOLERANCE OF ACCELERATION MAKES IT IMPOSSIBLE FOR A FAST AEROPLANE TO FOLLOW A SLOW ONE IN A TIGHT TURN.

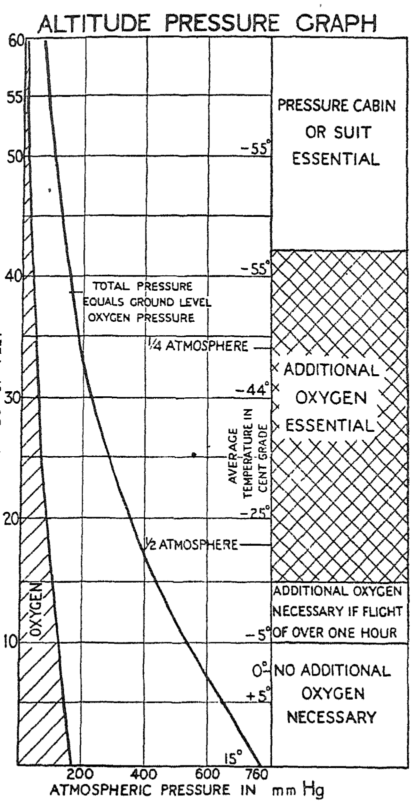

Fig. 4. Relationship between altitude and atmospheric pressure (I.C.A.N. scale).

pressure acting on man. When Flight-Lieut. Adam broke the world's altitude record by reaching 54,000 ft. in 1937, he wore a pressure-suit which was blown up to some $2\frac{1}{2}$ lb./sq. in. pressure and filled with pure oxygen. In it man could survive even in a vacuum. Thus the effects of oxygen-want can be completely overcome up to altitudes of some eight miles by breathing pure oxygen, and this is done in military aircraft of all nations. Above this height, pressure must be applied in addition. In the altitude record balloon ascents by Prof. Piccard and by the U.S. Army, closed gondolas at raised pressure were used.

Fig. 5 illustrates the time elapsing between cutting off the oxygen supply to a man and his becoming unconscious at various heights. From this it will be realized how quickly a pilot must act should his oxygen supply fail at high altitudes.

The physiological abnormalities at altitude are not entirely solved by breathing oxygen, as there are effects on the body at low pressure in addition to oxygen-lack. At ground-level the air pressure drives nitrogen into the blood which dissolves in appreciable quantity. If now the pressure on the man is rapidly reduced before this nitrogen can escape, it will form bubbles in his blood vessels and stop the circulation.

The possibility that bubbles might occur in animals at low pressures was envisaged in 1670 by Robert Boyle, who placed a viper under a bell-jar and pumped out the air; when the pressure was reduced he saw a bubble within the eye of the viper. Bubbles forming in the body fluids have long been a difficulty in deep diving where men have been subjected to much increased pressures of air. The body fluids then dissolve a large quantity of nitrogen, and if the diver comes to the surface too rapidly it cannot escape from his lungs in time to prevent bubbles forming, and he gets decompression sickness or 'bends' (caisson disease, compressed air illness), with severe pain, cramps, occasionally unconsciousness and even death. A diver can get severe bends coming up from a depth where the pressure is 4 atmospheres, to the surface where it is only 1 atmosphere, but fortunately an airman does not get into such serious difficulties if he goes from ground-level to one quarter ground-level pressure at 33,000 ft. Bends as they occur in the air are rarely experienced at altitudes below 25,000 ft. They come on slowly and are rarely of a serious nature. Unconsciousness can result if the warning symptoms of pain in the joints are neglected. The pains are cured almost instantly if descent is made to about 25,000 ft., where the air pressure compresses the bubbles sufficiently to drive them back into solution in the blood.

Much research has been carried out on men in decompression chambers to find ways of alleviating these effects. One method is to breathe pure oxygen before ascent so as to replace the nitrogen in the blood with oxygen. The oxygen is then used up in the tissues before it can form bubbles. This method has long been used to displace nitrogen from the blood while ascending from deep dives.

There are other disturbances to man with rapid changes of altitude resulting from the change in air pressure. The middle ear communicates through the eustachian canal with the throat and it is necessary for air to leave and enter it with ascent and descent lest the ear-drum be collapsed. The canal to the throat will normally open on swallowing, and in a dive a pilot clears his ears almost unconsciously; but should he fail to do so or have severe catarrh, he may damage his ear-drums. Enclosed gas elsewhere in the body, as in the sinuses surrounding the nose, has to equalize its pressure as the altitude changes or severe pain may result. Again, the gas normally present in the intestines expands to a larger and larger volume as the outside pressure falls when climbing, but this is rarely a serious practical problem.

Thus the human safety limit in height is some 10–16,000 ft. breathing air and 40–42,000 ft. breathing oxygen; heights much in excess of the latter are only achieved by enclosing the pilot in an artificial atmosphere.

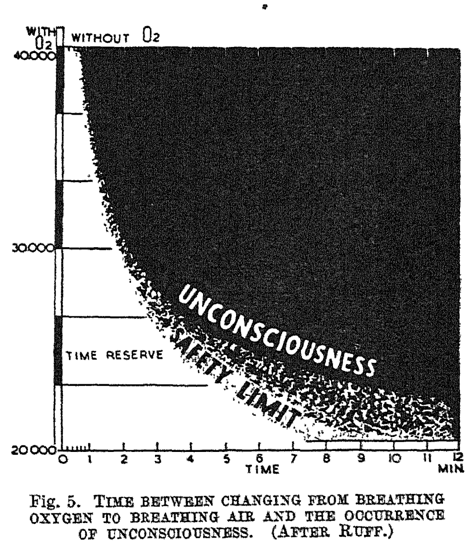

Fig. 5. Time between changing from breathing oxygen to breathing air and the occurrence of unconsciousness. (After Ruff.)

It is clear that, starting with fit pilots on the ground, much must be done to keep them efficient in the air, and the efficiency of the man may often be of even greater importance than that of the machine.

In the Battle of Britain quality in men and machines overcame weight of numbers, and although always greatly outnumbered, the R.A.F. by efficiency and courage were able to rout the Luftwaffe. To maintain that efficiency in the air and at high altitudes is no mean problem. That it is done is the result of scientific research during the last seventy years into life at great altitudes, and the successful application of what has been discovered to the particular problems of the pilot. I should like this lecture to be considered a tribute to all those scientific men, from Paul Bert onwards, and to many officers of the R.A.F. who have contributed so much to the solution of high-altitude flying, and in particular to those medical officers who have lost their lives in this War in flying experiments.

CONTROL OF OVULATION IN FARM ANIMALS

By JOHN HAMMOND, JUN.
School of Agriculture, Cambridge

WHEN Cole and Miller[1] obtained ovulation in ancœstrous sheep there was initiated a series of studies upon the application of gonadotrophins to the improvement of animal husbandry. It is the purpose of this article to sketch out the practical problems and the progress which has been made in overcoming them. It is not practicable to quote extensively, but many of the references to experimental work, upon which this account is based, are to be found in three papers in the *Journal of Agricultural Science*[2,3,4].

The nature of the control over ovulation which it may be desirable to exercise varies with the species and the economic circumstances. The problem may be to obtain matings outside the normal breeding season, or to improve fertility by increasing the number of ova shed at a normal heat, to regulate the interval between mating and ovulation, or to treat sterility due to cystic ovarian follicles. If a method of control is to be widely applied, it is necessary that the treatment be based upon materials which are available in large amounts and which are inexpensive to produce. Such preparations are at present limited to mare serum gonadotrophin, stilbœstrol and other synthetic œstrogens, and (available to a lesser extent) chorionic gonadotrophin and some pituitary extracts.

In the sheep, the natural breeding season falls in the autumn and winter months, but the length of the season varies considerably with different breeds, and in some, notably the merino and Dorset horn, it may extend over the whole or greater part of the year. The breed kept is determined by its suitability to local conditions, the relative value of the meat and wool crops, and, where rainfall is such that feeding conditions are good only in autumn or winter, mating has to be done in spring or summer, so that a breed with a long season is essential.

The incidence of twinning varies considerably from breed to breed; more especially it is low in the wool breeds. Specialized wool breeds are kept mainly in the more remote areas of the globe, and the lamb crop may be relatively unimportant; however, as meat storage and transport facilities are improved, it becomes of increasing value. When, as in Great Britain before the War, there is a price stimulus to the production of early lambs, or when seasonal conditions require it, the ram may be put with the ewes at the start of the breeding season. As some ewes come on heat earlier than others, the lambing season may then be prolonged and labour costs consequently increased. When the sheep are kept primarily for meat, the production costs include, besides the feeding of the lambs, the maintenance for a year of the ewes. The more lambs a ewe can rear the lower is the cost of production; it is certainly desirable that she should produce twins and, if the feeding stuffs are available, it may be of advantage to breed twice a year, which is not normally possible when the breeding season is restricted.

Thus in certain circumstances it may be of advantage to induce pregnancy in the normal ancœstrous period, to advance the onset of the breeding season or to increase the ovulation rate within the normal season. It is certain that by a policy of selection, twinning percentages could be much improved, and probable that, though with much more difficulty, the breeding seasons could be extended. Such methods, however, take a long time; meanwhile, hormone treatments offer a prospect of a rapid improvement in practice, pending the improvement in livestock which must be the ultimate aim.

In cattle the breeding season extends throughout the year, though there is a tendency for calving to shift to the spring. Heat periods tend to be shorter and less well marked in the winter, and there are two types of ancœstrus. In the first, ovulatory cycles continue, but heat is not manifested; in the second, a true ancœstrus, ovulation ceases and only small follicles are present in the ovaries; the latter state is almost entirely restricted to young animals in the winter months and under hard feeding conditions. The incidence of twinning is low, on the average well under 2 per cent, and is much lower in beef than in dairy breeds.

For milk production, calvings have to be spread over the year, and to maintain the winter supply a larger proportion must calve in the autumn months. This implies service in winter, when the ancœstrous condition is liable to develop. Sterility also causes large losses to the dairy industry, and a proportion of this is due to the formation of follicular cysts. Because in cattle the female twin to a male is usually a freemartin (imperfectly developed and sterile) twinning does not increase the number of animals which can be kept for breeding. In dairy cattle twins are not wanted, but in beef breeds they would be valuable for the same reason that applies to the mutton breeds of sheep. In areas where both beef and dairy cattle are kept, it is common for an extra calf to be bought for the cow to rear; however, the dairy-bred calf is a less efficient converter of feeding stuffs. In exclusively beef-producing areas there are, of course, no extra calves to buy.

The breeding season of the mare falls in spring and summer; persistence of ancœstrus causes some difficulty, and some sterility is due to development of cystic follicles, which may be associated with spiteful behaviour. The most important feature is, however, the low proportion of services which are fertile; this is attributable to the length of œstrus relative to the survival time of sperm. Ovulation occurs about a

day before the end of heat, and early in the season heat periods may sometimes last several weeks. With heavy horses a stallion may be available only once a week, so mating cannot be arranged at the optimum time even when the time of ovulation can be estimated.

The number of goats kept has increased during the War; partly because of milk rationing, partly because of the great variety of roughages upon which they will subsist. The breeding season is restricted, as in the sheep, and the gestation period is five months, so the peak of lactation cannot, with normal mating, be arranged to fall in winter when the milk ration is lowest. Mention must also be made of the pig. No work appears to have been done on the control of reproductive processes in this species. A method of increasing fertility would be valuable in some breeds, but the proper approach to this is probably the reduction of fœtal atrophy rather than increasing the number of ova shed.

In the mare and the cow, the condition of the ovaries can be ascertained by palpation per rectum. The structure of the ovary in the mare does not permit recognition of the corpus luteum, except in its early formative stages; but in the cow it is easily distinguished and can be removed by pressure without difficulty. After expression of the corpus luteum, heat and ovulation follow in about four days, and the cycle thus begun is of normal length. In the other species mentioned, the condition of the ovaries will depend upon the breed, age, time of year and time of the last heat period; it is probable also that nutritive conditions considerably affect the amount of follicle development. There is little precise information on these points. Year-old sheep (Suffolk and Suffolk crosses) killed in Cambridge are usually found to have well-developed follicles at all times in anœstrus; isolated ovulations are occasionally observed. The state of the ovaries during lactation is not known.

Mare serum gonadotrophin and follicle-stimulating pituitary extracts will cause follicle growth, followed by ovulation, in anœstrous sheep. The first ovulation of the breeding season in sheep is not normally accompanied by heat, and this also applies to gonadotrophin-induced ovulation. Injection of mare serum gonadotrophin combined with artificial insemination may lead to pregnancy; but as yet this has been achieved in only a small proportion of the treated animals. The number of ovulations is normal and seems, except possibly for very high doses, to be unrelated to the amount of gonadotrophin given. Treatment with stilbœstrol and other œstrogens will cause heat, and in some cases, probably those animals with larger follicles, also leads to ovulation. When stilbœstrol and mare serum gonadotrophin are given together it appears the œstrogen may sometimes inhibit the ovulation which would be obtained with the gonadotrophin alone; often with œstrogen the time relationships of œstrus and ovulation have been such as to render fertilization improbable.

If a second follicle-stimulating treatment is given after an interval of about sixteen days (the normal cycle-length in sheep), heat and fertile service often follow. An induced ovulation is sometimes followed, a cycle later, by spontaneous ovulation together with heat. The difficulty may be encountered in the summer that the ram is not at all keen. The numbers coming on heat after a double treatment have, in trials, varied greatly from flock to flock and year to year; the proportion of services fertile is lower than in the breeding season. Results tend to be best with fifteen-month-old animals and poorest with suckling ewes. Much remains to be done before commercial application is possible.

The goat appears to differ from the sheep in that about half come on heat a few days after a single injection of mare serum gonadotrophin[5]; the proportion of services which are fertile is lower than in the breeding season. In anœstrous heifers, only small follicles are present in the ovary, and stilbœstrol does not induce ovulation, though, of course, it produces signs of heat. Mare serum gonadotrophin and horse pituitary have been found to cause follicle growth followed by ovulation in the majority of animals, though a small proportion fail to respond. Heat is not always shown and tends to be short and not well marked; in those served, the frequency of conception seems to approach the normal figure. In the mare, it is noteworthy that mare serum gonadotrophin, characteristically follicle-stimulating, has no apparent effect on the anœstrous ovary[6], and at present there is no practicable and effective treatment.

In the breeding season, the presence and influence of the corpus luteum may be responsible for a different response to treatment from that found in anœstrus. In sheep and cattle, the luteal phase occupies nearly the whole of the cycle. Stilbœstrol given in mid-cycle will produce signs of heat, but usually without willingness to accept the male, and the rhythm of the cycle is unaffected. Chorionic gonadotrophin will cause ovulation in the presence of a corpus luteum, follicle-stimulating preparations may sometimes do so, but not generally. Usually the cycle rhythm is unaltered; the corpus luteum formed when ovulation is induced in mid-cycle persists only as long as that already present in the ovary. If gonadotrophin is given shortly before the corpus luteum degenerates, the follicles developed, but previously restrained from ovulating, do so at the next heat period. In this way an increased ovulation-rate is obtained. In sheep, this has been confirmed by several workers, and multiple pregnancies have been so produced; practical trials have, however, given very disappointing results.

In the cow, multiple ovulations and calvings have been obtained in this way with mare serum gonadotrophin. They may also be obtained by injection of this gonadotrophin earlier in the cycle, followed by expression of the corpus luteum, the number of ovulations varying with the dosage and the interval between injection and removal of the corpus luteum. Little has yet been done to determine how closely the number of ova shed can be controlled, but it seems, at least when a single injection is given, that the corpus luteum removal method may be not sufficiently dependable, and the end of cycle injection may be satisfactory if the time for treatment can be properly judged. The former method requires only a rectal examination, the latter that the cow be seen on heat previously; with beef cattle it is usual for the bull to be run with the herd, and heat is not well marked. An increased frequency of double ovulations has been noted in cattle after treatment with stilbœstrol implants[7], so it may be possible to evolve a method of increasing the ovulation-rate by the use of œstrogens.

Lastly, mention should be made of conditions in which there is a large follicle present and no active corpus luteum. After rupture of a cystic follicle in the cow, a follicle usually matures but, failing to

ovulate, also degenerates into a cyst. If this follicle is ruptured early, it undergoes luteinization and the normal cycle is resumed. Chorionic gonadotrophin, at least in some cases, will cause ovulation of such follicles[6]; this treatment may be useful because it can be given by one without the necessary skill in rectal examination. Chorionic gonadotrophin given to œstrous mares having a large follicle induces ovulation within about twenty-four hours; prolonged œstrous periods are thereby terminated and matings can be arranged accordingly.

In this short account, it has been convenient to give only a few references, mostly English; it is therefore well to point out that much work in this field, particularly early attempts at application to sheep breeding, has been Russian, most of the remainder being done in the United States and Great Britain.

THE STATISTICAL LAW IN NATURE

By Prof. ERWIN SCHRÖDINGER

Dublin Institute for Advanced Studies

LUDWIG BOLTZMANN was born in Vienna in 1844. Of the Austrian tetrad of brilliant physicists (Loschmidt, Stefan, Mach, Boltzmann) he duly gained widest fame. I could begin by telling of the splendid, at that time daring, proof he gave of the fundamental law of radiation, by imagining a pintful of nothing to undergo a sequence of compressions and dilatations—a so-called Carnot cycle. I could tell of his grinding a crystal of sulphur to the shape of a neat marble, that was to serve him in an experimental confirmation of Maxwell's theory of electricity, of which he was one of the foremost champions on the Continent. But to indicate what he really meant to the development of human thought, I must start from a wider basis.

In the course of the last sixty or eighty years, statistical methods and the calculus of probability have entered one branch of science after another. Independently, to all appearance, they acquired more or less rapidly a central position in biology, physics, chemistry, meteorology, astronomy, let alone such political sciences as national economy, etc. At first, that may have seemed incidental: a new theoretical device had become available and was used wherever it could be helpful, just as the microscope, the electric current, X-rays or integral equations. But in the case of statistics, it was more than this kind of coincidence.

On its first appearance the new weapon was mostly accompanied by an excuse: it was only to remedy our shortcoming, our ignorance of details or our inability to cope with vast observational material. In the study of heredity we might prefer to be able to record the individual processes of meiosis, and thus to know how the hereditary treasure of a particular individual is composed from those of its grandparents. In text-books on gas-theory it has become a stock-phrase, that statistical methods are imposed on us by our ignorance of the initial co-ordinates and velocities of the single atoms—and by the unsurmountable intricacy of integrating 10^{23} simultaneous differential equations, even if we knew the initial values.

But inadvertently, as it were, the attitude changes. It dawns upon us that the individual case is entirely devoid of interest, whether detailed information about it is obtainable or not, whether the mathematical problem it sets can be coped with or not. We realize that even if it could be done, we should have to follow up thousands of individual cases and could eventually make no better use of them than compound them into one statistical enunciation. The working of the statistical mechanism itself is what we are really interested in. It adds nothing to our outlook to know whether a particular (male) fly owes a specified portion of its X-chromosome to its mother's father or to its mother's mother. The relevant fact is, that one or the other must be the case and that one is as likely as the other.

I dare say the first scientific man aware of the vital role of statistics was Charles Darwin. His theory hinges on the law of big numbers. He had not to resort to heavy mathematics; common sense is sometimes an admirable substitute. It will be remembered how untiringly Darwin emphasizes again and again the enormous geometrical progression of virtual offspring and the enormous destruction of actual offspring that must be inferred therefrom. This, indeed, is the statistical mechanism which makes practically and safely operative the very small increase in chance of survival that a small favourable variation entails.

More drastically than any other science, physics has promoted the statistical aspect from an ancillary service to the domineering role of indicating the goals and pointing out the pathways. It was a revolutionary step, affecting virtually the whole house of science, inasmuch as it is ultimately based on physics. The names of L. Boltzmann and W. Gibbs are representative of that discovery. Only five years in age separated these two men, of whom Gibbs was the older; but the Atlantic lay between them, and I do not know that they ever met. Yet so parallel ran their thought, that to us it almost coalesces. It involved a new outlook on the nature of the laws of Nature; namely, that they are not rigorous laws at all, but 'only' statistical regularities, based on the law of great numbers, just as Darwin's theory is*.

Among the laws of physics *one* has quite a unique standing, the so-called Second Law of Thermodynamics. By enunciating (in a sense not to be detailed here) the *perpetual increase of entropy*, it safeguards a one-way traffic of physical events. Nothing could ever happen in exactly the opposite way it does happen, because that would involve a decrease of entropy. No substantial part of the world can ever be made to run backwards, as you could do with an ideal, purely mechanical clock-work (which, of course, does not exist). The Second Law embodies the unidirectional trend, the irreversibility in the course of Nature.

It would scarcely be satisfactory to account for this remarkable fact by inventing some special device, to be attributed as a common feature to all the

* If the nineteenth century is going to be named after any one man, said Boltzmann in 1886, it will be called the century of Darwin.

multifarious 'mechanisms' in Nature. According to Boltzmann, this is not necessary. The Second Law rests on—nay, it *is*—statistics; it is the pure embodiment of the statistical law itself, nothing else. Events move in the direction in which they are most likely to move. Heat flows in the direction of temperature fall, because it is billions of billions times less likely to do anything else.

The philosophical implication can scarcely be overrated. Forces, charges, potentials, collisions—the whole armoury of detailed mechanisms we invent—are apt to retain, in spite of all our striving for the contrary, a slightly mystic tinge or at least much arbitrariness. Boltzmann's discovery, though it cannot entirely dispense with this armoury, assigns to it the rank of an auxiliary device. Our true understanding of what happens is reduced to reasoning about *whole numbers*. We are able to predict the course of events, because we are able to count: one, two, three four, . . . so we can count the eventualities of every thinkable turn and find out the one that is overwhelmingly likely.

That the probability is, as a rule, next to certainty —in other words, that the laws of Nature are next to infallible—is due to the enormous number of single atoms or single microscopic events that co-operate. Whenever this number is not 'enormous', deviations must be expected. From the very year of Boltzmann's tragic death (1906) experimental evidence about these 'thermodynamic fluctuations' began to spring up abundantly, confirming quantitatively the conclusions from his theory, none of which has ever failed.

In the long run, even very improbable things are bound to happen. Given an infinity of time, a physical system would return occasionally even to a very improbable state. Strangely enough, the overwhelmingly most probable manner of accomplishing the—in itself extremely improbable—return is by an *exact* reversal in time of a common process, one following the ordinary laws of physics as we know them. In a word, *sub specie æternitatis*, past and future become equivalent—there is no 'arrow of time'. Future may mean nothing more than just that one of the two directions of time in which entropy does increase—in our time and for some time before and after. This curious result, of which a momentous effect on our world-picture may still be in store, is the inevitable outcome of sober mathematics, not a wilful day-dream.

While many a page in Boltzmann's books and scientific papers is witness to his unusual, slightly capricious, but very lovable human personality, the most attractive means of reconstructing it is offered by the slim volume of his popular writings[1]. I wish I could use up another column or two in quoting from these enjoyable essays. "A German Professor's Voyage to the Eldorado"—describing a visit to California—is a gem in light literature (the use of "German" in the purely cultural connotation was, of course, current in Vienna). The new topic of aeronautics, the objective existence of the world around us, controversies on the ill-famed German 'energetics', Beethoven's symphonies, America's university life and queer temperance laws, and scores of other subjects are dealt with in this volume in a pleasing conversational tone by one who was a man, take him for all in all—with a candid soul, a sincere and interesting mind, whatever else he might have been.

OBITUARIES

Mr. H. N. Dixon

HUGH NEVILLE DIXON was born at Wickham Bishops, Essex, on April 20, 1861, and died at Northampton on May 9, 1944. He was educated at Christ's College, Cambridge, where he studied classics, taking a first in the Classical Tripos in 1883; he later obtained a London M.A. On leaving Cambridge he went to assist the Rev. Thomas Arnold, who had a school for the deaf at Northampton, which his brother attended; he succeeded as head of the school in 1884, retiring in 1914. He was an active Congregationalist serving on many committees, and was a director of the London Missionary Society.

In 1886, Dixon became secretary of the Northamptonshire Naturalists' Society and Field Club and took an active part in its affairs until his death, continuing as secretary until 1931. An all-round naturalist, he was mainly interested in mosses. His first paper, "Northamptonshire Mosses", appeared in the *Journal of Botany* for 1884, and was preceded by a note on "New Localities for Rare Mosses" which gave evidence that his interest dated from his Cambridge days. Then, until the end, there was a steady stream of papers, first on British and European mosses, and then those of various expeditions to different parts of the world until he became, and was regarded as, one of the foremost authorities on the group. He is best known to students by his excellent "The Student's Handbook of British Mosses", which was published in 1896, with further editions in 1904 and 1924. This was illustrated with drawings by the Rev. H. G. Jameson, who also drew up keys to the genera and species. This is the standard Flora and is likely long to remain so. His only other book is "Studies in the Bryology of New Zealand", which appeared in parts during 1913–29 and has "special reference to the herbarium of Robert Brown", the shoemaker bryologist of Christchurch.

With so many calls on his knowledge Dixon might well have pleaded inability to give assistance to those struggling with identifications of common British mosses; but it was characteristic of him that he always gave unstinted assistance and encouragement. He joined the Moss Exchange Club on its formation in 1896, and when it was converted into the British Bryological Society in 1923, he was appropriately elected as the first president: he had produced a "handbook" catalogue of British mosses for use of members in 1897.

H. N. Dixon was quiet and unassuming, of wide learning and, except where his principles were offended, a man of peace. He was fond of sketching, and wrote quite pleasing verse. Few, until they knew him well, realized his store of energy; he was an adept at skating, played hockey until he was more than fifty, climbed Snowdon three times in one day, and Skiddaw on his eightieth birthday—with alpine climbs to his credit; and walked from Northampton to Leamington, Kenilworth and Coventry—55 miles in one day.

Dixon's health did not begin to fail until this year. So late as March he read a short paper before the Linnean Society on "The Phytogeographic Relations of Sumatran and other Alpine Mosses"—and was engaged on naming some British Museum collections when he became ill. Thus for sixty years H. N. Dixon published a long series of important papers on the taxonomy of mosses, and his name is writ large in

the annals of bryology. He served on the Council of the Linnean Society during 1925–29, and was vice-president in 1928. He was honorary member of several natural history societies, but none of the recognized honours came his way. Perhaps it was because taxonomy, not being in the fashion, is not 'original research'—perhaps it was because he was over-modest. He has bequeathed his British collection to the Kew Herbarium and his foreign collection to the British Museum (Natural History). J. RAMSBOTTOM.

WE regret to announce the following deaths:

Prof. J. G. Duncan, lecturer in chemistry in the Royal Technical College, Glasgow, and professor of chemistry at the Veterinary College, Glasgow, on May 1.

Prof. Chancey Juday, emeritus professor of limnology and director of the Limnological Laboratory at the University of Wisconsin, president in 1927 of the Ecological Society of America, on March 29, aged seventy-two.

NEWS and VIEWS

University Chair of Geography: Birkbeck College

Prof. E. G. R. Taylor

THE retirement of Prof. Eva G. R. Taylor from the University chair of geography at Birkbeck College, London, marks the departure from active academic life of one of the most vigorous personalities in geography. After graduating in natural sciences in London, she became personal assistant to Prof. A. J. Herbertson at Oxford at a time when he and his contemporaries—including Halford Mackinder and H. R. Mill—were laying the firm foundations of the modern concept of geography. A period of lecturing in London teachers' training colleges followed by ten years association (1921–31) with Prof. J. F. Unstead at Birkbeck College gave opportunities, both through lively teaching and lecturing and the well-known series of Unstead and Taylor text-books, for disseminating the new ideas in the minds of successive generations of prospective teachers. Prof. Taylor preferred always to work under her maiden name, but geographical work had to be combined in these years with the urgent needs of a young family; nevertheless she found time for a thoughtful little book on "Oceans and Rivers", and in her own text-books developed the now universally familiar idea of the 'sketch-map'—more adequately described as a cartogram in which certain salient or related features are selected for diagrammatic representation on an outline map.

Prof. Taylor's appointment in 1931 to succeed Prof. Unstead gave opportunities for a wider sphere of work. Earlier years of patient research in historical geography led to the successive publication of a study of Barlow's "Brief Summe of Geographie", comprehensive works on Tudor geography and on Late Tudor and Early Stuart geography and on the writings of the Hakluyts. Papers on old maps and instruments appeared in the *Mariners Mirror* and many other journals. In 1937 came the great opportunity to bring before a wider public the geographical concept of the influence of environmental factors in the life of man. The Royal Geographical Society was asked to prepare evidence for the Royal Commission on the Geographical Location of the Industrial Population (the Barlow Commission) and Prof. Taylor acted as chairman of the committee which, by a large series of maps and diagrams yet to be incorporated in the proposed National Atlas, succeeded in demonstrating both the strength and permanence of such localizing factors as accessibility, relief of the land, distribution of minerals, soil, rainfall, temperature, fog and a host of others on the distribution of industry and the movement of the population. She showed the dangers of the growing concentration of industry and population in a central coffin-shaped area stretching from Lancashire to Greater London—with the consequent creation of peripheral depressed areas. With Dr. Dudley Stamp she represented the Society and gave verbal evidence to the Commission the influence of which is apparent in both the Barlow Report and the subsequent Scott Report, as well as in what is now current day-to-day practice in town and country planning. It is greatly to be hoped that Prof. Taylor's retirement will in reality mean greater leisure for continuance of constructive work.

Prof. S. W. Wooldridge

DR. S. W. WOOLDRIDGE, who has been appointed to succeed Prof. Taylor, was trained as a geologist. He took as his special field the minor structures and glacial history of the London Basin, to which much of his published work relates. The climatic implications of glaciation drew him to a study of meteorology under the stimulating guidance of Sir Napier Shaw, and, thus equipped, it was natural that he should be invited to lecture on the physical basis of geography to the newly formed Honours School of Geography at King's College and the London School of Economics. Dr. Wooldridge's attention was thus turned to human geography, concerning which its critics said that its conclusions were either trivial or fallacious. To test this view, he examined the archæological and historical material relating to the entry phase of the Anglo-Saxon settlement in the light of his geomorphological researches, and was able to demonstrate, *inter alia*, the important influence of the loam terrains. His published papers on this theme strengthen the view that the weakness of human geography has arisen rather from the insufficient refinement of the analysis of physical conditions than from the unimportance of the geographical factor. At Birkbeck College Dr. Wooldridge will find a considerable body of postgraduate students, many of whom are at work on geographical aspects of regional and national planning. The importance of a close scrutiny of the terrain in this connexion needs no emphasis.

Ardaseer Cursetjee (Wadia), F.R.S.

FEW men of science in Great Britain know that an Indian, Ardaseer Cursetjee (Wadia), was admitted into the fellowship of the Royal Society so early as 1841. The following information was given to Prof. A. V. Hill, biological secretary of the Royal Society, by Colonel S. L. Bhatia, of the Indian Medical Service, who obtained details from Sir R. P. Masani of Bombay. In the *Journal of the Royal Asiatic Society* of 1865 he appears as "Ardeseer Cursetjee, Esquire, of Bombay" and as the first Indian elected a fellow of

the Royal Society in the records of that Society. There is corroboration in "History of the Lodge Rising Star of Western India" by D. F. Wadia. "It was at the very meeting (of the Lodge) held at the Town Hall on 15 December 1843, that four gentlemen were proposed for initiation to be ballotted for at the next meeting. They were Mr. Ardeseer Cursetjee Wadia (the first native gentleman admitted a Fellow of the Royal Society, who had a great engineering reputation and was at this time Chief Engineer in the Government Dockyard) and Messrs. Mirza Ali Mahomed Shoostry, Hajee Hasham Ishphanee and Mahomed Jaffer, who were leading Mogul Mahomedan merchants of the day."

In 1822 Ardaseer Cursetjee (Wadia) served under his father in the Government Dockyard and became assistant builder. In 1833 he built a small steamer, the *Indus*, in the Mazagon Dock and personally fitted up all machinery. He is reported to have made experiments in connexion with gas lighting and to have fixed up all pipes and gas machinery in his bungalow at Mazagon, Bombay; and it is recorded in Parsi annals that the Earl of Clare, Governor of Bombay, inspected the installation on March 10, 1834, and gave him a 'Dress of Honour'. In 1836 he was appointed non-resident member of the Royal Asiatic Society of Great Britain and Ireland. In 1839 Ardaseer Cursetjee (Wadia) went to England for further studies in mechanical engineering. There his services were engaged by the court of directors of the East India Company in the workshop of Messrs. Wards and Keppel. The chronicles further state that he was presented to Queen Victoria on July 1, 1840, and that he thereafter published a book of his notes regarding his travels in England. He returned to Bombay in 1841 and was appointed chief engineer of the Steam Factory and Foundry. In 1849 he was elected vice-president of the Mechanics Institute. He went to England for the second time in 1851; was made a Justice of the Peace in 1855, and retired on pension on August 1, 1857. In 1859 he went to England for the third time; and in 1861 he was appointed chief resident engineer of the Indus Flotilla Company at Karachi, and there he built three or four steamers navigating the Indus. In 1864 he went to England for the fourth time and remained there until his death on November 16, 1877, at the age of seventy.

'Marfanil'

LITTLE has been gleaned, according to the *Lancet* (635, May 13, 1944), from a close watch on German medical publications and practice during this War; but an exception is 'Marfanil', formerly known as 'Mesudin', which is 4-amino-methyl-benzene sulphonamide. It differs from the other common sulphonamides in having the amino group separated from the benzene ring by a methyl group. It is now extensively used in the German army for local application to wounds, being issued as a powder; the powder is used either alone or diluted with nine parts of sulphanilamide. Tablets of equal parts of 'Marfanil' and sulphanilamide are also used. A quantity of the drug captured in North Africa has been tested clinically by three R.A.M.C. officers, Lieut.-Colonel G. A. G. Mitchell, Captain W. S. Rees and Captain C. N. Robinson, who give their results in the same issue of the *Lancet*. They say that no other substance that they have tested has given better results, except penicillin; and they suggest that penicillin used in conjunction with 'Marfanil' may give better results than penicillin mixed with sulphanilamide or sulphathiazole. The anti-bacterial action of 'Marfanil' is not inhibited by pus or other wound discharges. It is almost non-irritating, and is no more toxic than sulphanilamide. It does not destroy epithelium or prevent its growth. It is evident from the other features of this drug discussed by the *Lancet* that further study of it would be profitable. It is, unfortunately, largely inactivated in the blood and is therefore not suitable for systemic administration; but it should not be beyond the skill of chemists to overcome its other drawback, namely, the difficulty of producing it in quantity.

Herbs and Medicinal Plants

DURING the past year, the *Brooklyn Botanic Garden Record* (32, Nos. 1 and 3) included two attractive Guides (Nos. 15 and 16) to the Herb and Medicinal Garden which was opened in 1938. The provision of a medical plant garden was considered justified in view of the large number of plant drugs in use in spite of the recent increase in the number of 'chemical' and 'biological' substances utilized in medical practice. Guide No. 16 includes a survey by A. H. Graves of the use of plants in medicine from Greek times up to the present day, which illustrates the growth of our knowledge from the relatively advanced outlook of the Greeks, through the period clouded by superstitions of the early Middle Ages, finally to the very marked advances of modern times. This survey is written in a style to attract the interest of general and scientific readers, and is illustrated by numerous woodcuts of the activities of the early herbalists. The historical survey is followed by an account by Prof. C. W. Ballard of Columbia University, and collaborators, of the medical uses of the species commonly regarded as drug plants. In the case of some of those officially recognized in the United States Pharmacopeia or the National Formulary, such as *Aloe vera, Ephedra equisetina, Atropa belladonna*, etc., some indication of the amount used annually and the possibilities of home cultivation within the United States receive comment. In the case of some imported plant drugs, the shortage caused by the present crisis has indicated clearly that the encouragement of home cultivation of the plants and their study with a view to possible synthesis of the medicinal constituents is a matter worthy of serious consideration.

Vesalius and the Struggle for Intellectual Freedom

IN an address delivered before the Washington Academy of Sciences on November 18, 1943, on the occasion of the four hundredth anniversary of the publication of Vesalius's "De humani corporis Fabrica" (*J. Wash. Acad. Sci.*, 34, 1; 1944), Prof. Howard W. Haggard, of Yale University, sees the great classic of human anatomy as less important for its merely technical contents than for its significance in the struggle for intellectual freedom, for the liberty of scientific thought against tradition and authority. Reviewing the progress of medical knowledge through the centuries, he shows that the authority of Galen had helped to blind even competent observers to the facts revealed on the dissecting table until Vesalius published his great book in 1543. Prof. Haggard deals also with the main facts and incidents in the life of Vesalius, and his tragic death from an unknown disease when shipwrecked on the island of Zante on returning from a pilgrimage

to the Holy Land and on his way to resume his old chair of anatomy in Padua. There is also a reference to another tragedy, that of Servetus, "who, for a theological quibble, was burned at the stake by order of Calvin and whose books were burned with him"—a crime of bad faith that still sends a cold shudder through the sensitive reader.

New World Prehistory

A PAMPHLET entitled "Cross Sections of New World Prehistory: a Brief Report on the Work of the Institute of Andean Research, 1941–42", by Wm. Duncan Strong, professor of anthropology at Columbia University, has been issued (*Smithsonian Misc. Collections*, 104, No. 2). The fields covered by the various investigators include eastern and western Mexico, El Salvador, Venezuela and the West Indies, Colombia, Ecuador, various districts in Peru and the northern coast of Chile. Naturally the information from such a wide area of the Americas that can be given in some 42 pages accompanied by 33 plates is not very extensive; but a general survey like this is of value, and the large relative chronological chart from A.D. 100 to A.D. 1500 will doubtless prove useful to students more interested in the general prehistory of Central and South America than in its details. There is also a map showing the general location of the excavations undertaken by the Institute.

Remote Switching by Superimposed Currents

A PAPER was read on this subject in London recently before the Institution of Electrical Engineers by J. L. Carr, in which the author briefly reviewed the methods employed for the centralized control of switching operations on distribution networks, by the injection into the distribution system of currents the frequencies of which differ from that of the main supply. The superimposition of ultra-audio frequencies for limited and specific purposes, such as the protection or the remote switching of a transmission line, has not, so far, been employed to any large extent in Great Britain, and is therefore not considered. Several devices employed to respond to injection currents are briefly described, and the probable applications of this method of control are outlined. Particulars of the development of remote signalling over the network of a large electricity supply undertaking are given, together with reasons for the final adoption of the method selected. Data of the components of the equipment are given, and the power required is analysed for two frequencies.

Recent Earthquakes

THE United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has found the epicentres of three recent earthquakes. On January 10 at 20h. 10·0m. G.M.T., an earthquake had its epicentre in Mexico near lat. 18·1° N., long. 100·6° W. It was recorded throughout America and as far north as Sitka in Alaska. On January 15 at 23h. 49·4m. G.M.T., an earthquake had its epicentre in the Argentine near lat. 31·5° S., long. 68° W. It was recorded throughout America as far north as Alaska and at Honolulu. On February 3 at 12h. 15·2m. G.M.T., an earthquake had its epicentre in south-eastern Alaska near lat. 59·3° N., long. 138·0° W. This was recorded by seismographs at Buffalo, Burlington, Chicago, Fordham, Georgetown, Honolulu, Pasadena, Philadelphia, Sitka and Tucson.

Lunar Eclipses and the Earth's Atmosphere

Sky and Telescope of January 1944 has a short notice with the above title, which describes the photometric results of the lunar eclipse on March 2–3, 1942. These results were obtained in France by Daniel Barbier, Daniel Chalonge and Ernest Vigroux, and indicated, in accordance with the theoretical predictions by Link, a relationship between the intensity of the ozone bands and the distance from the centre of the shadow. Future spectrophotometric studies of lunar eclipses may yield new information on the earth's upper atmosphere.

Physical Society

AT the annual general meeting of the Physical Society held on May 24 the following were elected or re-elected for 1944–45: *President*, Prof. E. N. da C. Andrade; *New Vice-President*, Sir Edward Appleton; *Hon. Secretaries*, Mr. J. H. Awbery (Papers) and Dr. W. Jevons (Business); *Hon. Treasurer*, Dr. C. C. Paterson; *New Members of Council*, Prof. S. Chapman, Mr. C. H. Collie and Prof. H. R. Robinson. At an extraordinary general meeting held on the same day A. F. Joffe was elected an honorary fellow of the Society. The officers of the Colour Group for 1944–45 are: *Chairman*, Mr. J. Guild; *Hon. Secretary*, Dr. W. D. Wright. The officers of the Optical Group for 1944–45 are: *Chairman*, Prof. A. O. Rankine; *Hon. Secretary*, Prof. L. C. Martin.

Announcements

PROF. A. V. HILL, biological secretary of the Royal Society, has been awarded the Joykissen Mookerjee Gold Medal for 1944 of the Indian Association for the Cultivation of Science.

SIR ARDESHIR DALAL, director in charge of the Tata Iron and Steel Co., Ltd., has been appointed a member of the Executive Council of the Governor-General of India, and will be in charge of a newly formed Department of Planning and Development.

Dr. B. A. Keen and Dr. E. B. Worthington, the two British members of the Scientific Advisory Mission to the Middle East Supply Centre, who have been travelling extensively in the Middle East territories for the past seven months, have returned to England for consultations at the Ministry of War Transport in connexion with their draft report and recommendations.

THE American Association for the Advancement of Science will hold its annual meeting for 1944 at Cleveland, Ohio, during September 11–16. Two previous annual meetings have been cancelled at the request of the U.S. Office of Defense Transportation.

AT the annual general meeting of the Institute of Physics held on May 22 the following were elected to take office on October 1: *President*, Sir Frank Smith; *Hon. Treasurer*, Major C. E. S. Phillips; *Hon. Secretary*, Prof. J. A. Crowther.

THE Summer School in Social Biology arranged by the British Social Hygiene Council to be held in Bangor (see NATURE, March 25, p. 373) has been cancelled.

Relaxation Processes in Statistical Systems

THE difficulties besetting the so-called 'foundation of statistics', that is, the establishment of the connexion between statistics and mechanics, reduce, as is well known, to two fundamental points of an entirely different nature.

The first difficulty is connected with the introduction into mechanics of probability conceptions, which constitute the essential feature of statistical physics, for example, of its fundamental assertion, the H theorem. The second difficulty consists in the mechanical specification of those systems to which the results of statistical mechanics can be applied.

To the first group belong all the problems of a mechanical interpretation of irreversibility, all the well-known objections against Boltzman's treatment of the H-theorem. To the second group belong the investigation of ergodical properties, which have met with but very meagre success in reaching the goal set by statistical mechanics. In spite of a number of accessory results—eventually extremely important ones—obtained in the attempts to overcome these two difficulties, the problem of establishing the connexion between statistics and mechanics must be considered as wholly unsolved thus far.

In fact, all these points of view, which were based on classical mechanics (Boltzmann, Ehrenfest, Mises, Rosenthal and others), are in principle incapable of overcoming the first of the above difficulties: all attempts to introduce into the classical mechanics the probability concept lead to inner contradictions. This circumstance is expressed by the fact that the mechanical process cannot be subjected to the probability scheme of Markoff's chains (Hadamard). (In particular, the interpretation of the H-theorem with the help of Boltzmann's famous saw-like curve proves to be self-contradictory.) On the other hand, investigations based on classical mechanics (numerous investigations of mechanical ergodicity carried out in recent years) have led to problems of unsurmountable complexity in the way of removing the second difficulty; in the first place, it turns out that mechanical ergodicity is quite insufficient for statistical purposes—and, in particular, for the definition of the fundamental notion of relaxation; in the second place, the results of investigations on ergodicity did not enable one to specify those systems to which the corresponding mathematical definitions should be applicable.

At the same time, attempts to solve the question based on quantum mechanics (Neumann, Klein, Pauli, Fierz and others) left the second difficulty altogether aside, referring to the model of irreducibility only. But even in this respect they could not reach their goal: the connexion between the microscopic and the macroscopic notions, indicated by them, remained unsatisfactory. Investigations based both on the classical and on the quantum point of view thus could not introduce the notion of the relaxation of a system, which is the fundamental notion of statistical physics: they not only did not give—even in principle—a method for a quantitative determination of the relaxation time, but left the notion of relaxation devoid even of a qualitative definition through the mechanical characteristics of the system. They were, accordingly, quite unsatisfactory.

In the present investigation, the notion of ergodicity is ignored. I reject the ergodical hypothesis completely: it is both insufficient and unnecessary for statistics. I use, as starting point, the notion of motions of the mixing type, and show that the essential mechanical condition for the applicability of statistics consists in the requirement that in the phase space of the system all the regions with a sufficiently large size should vary in the course of time in such a way that while their volume remains constant—according to Liouville's theorem—their parts should be distributed over the whole phase space (more exactly over the layer, corresponding to given values of the single-valued integrals of the motion) with a steadily increasing degree of uniformity.

It is possible to state the general condition which must be satisfied by the potential energy of the system for the latter to belong to the mixing type. The main part of this condition consists in the requirement that the curvature R of the Riemann space of Jacobi's variational principle, corresponding to the mechanical problem and expressed by the formula

$$R = -\frac{1}{hw^2}\Delta w - \left(\frac{1}{4} - \frac{3}{2h}\right)\frac{1}{w^3}\operatorname{grad}^2 w,$$

where $w = A\ (\varepsilon_0 - u)$, ε_0 is the total energy of the system, u its potential energy, A a certain constant, n the number of degrees of freedom, Δ and grad being defined in the n-dimensional configuration space[1], should be negative; or, more exactly, that the regions with a positive curvature should be sufficiently small. This condition is actually fulfilled in all the practically important cases of the application of statistical physics.

The main condition of mixing, which ensures the fulfilment of this condition, is a sufficiently rapid divergence of the geodetic lines of this Riemann space (that is, of the paths of the system in the n-dimensional configuration space), namely, an exponential divergence (cf. Nopf[1]).

Measurements of macroscopical systems, considered in statistical mechanics, refer to a region of phase space with a volume $A^n \gg h^n$ (this is due, besides the quantum character of the measurements, to the macroscopic character of the systems). The notion of probability penetrating all the statements of statistical mechanics arises as a result of the impossibility of specifying the state of the system as a point in the phase space. The change of the distribution function of the system is determined by the law of spreading of the points of the initial region over the whole surface of the given values of the single-valued integrals of the motion: the probability of finding the system at a time t after the initial experiment in a certain macroscopic state is defined by the fraction of the points of the initial region, which at the instant t are situated within the region, corresponding to this macroscopic state. In the presence of mixing, this circumstance ensures the fulfilment of all the probability requirements of statistical physics (of the H-theorem, of Schrödinger's reversibility of the macroscopic equations with respect to the time, etc.). The relaxation process can be visualized as the process of the mixing—the mixing of the initial region, corresponding to the original

non-equilibrium state, over the whole surface of given values of the single-value integrals of the motion. The relaxation time is defined as the time of this mixing, that is, the time during which a mixing with such a degree of uniformity is reached as corresponds to the type of the control macroscopic measurement, that is, to the accuracy of the experiment checking the establishment of equilibrium. The relaxation time depends, in general, on the type of the original fluctuation. The largest value of the relaxation time can be defined as the time of mixing of an initial region with a volume A^n, when $A \sim h$.

It turns out that the relaxation time possesses over a very wide range the property of being insensitive with respect to the size of the initial region A^n, tending, however, to infinity in the limit $A \rightarrow 0$, corresponding to a transition to the classical mechanics. From this insensitivity it can be concluded that with increase of the fluctuation the relaxation time increases very slowly, tending rapidly to the limit, corresponding to the minimum value of the region A^n (for $A \sim h$). In the case of an ideal gas, this limiting value of the relaxation time with respect to the velocities is given by the formula :

$$t = \frac{\frac{3}{2}\tau}{\ln \lambda/r_0} \left\{ \ln \frac{2\pi}{(\Delta p/p_0)} \right\},$$

where τ and λ are the duration and length of the mean free path, r_0 is the radius of a molecule, $p_0 = \sqrt{mkT}$, $\Delta p = A/L$, L is the linear dimensions of the system, and $A \sim h$; it thus proves to be of the order of a few τ. In a transition to the classical case, $A \rightarrow 0$ and $t \rightarrow \infty$. Under the condition $A \sim h$, the relaxation time can, however, depend on the choice of the initial region of this size. Since the space of 'initial regions', that is, of the results of the most complete experiments, is compact, it can be shown that the relaxation time for different initial regions of the same minimum size A^n possesses an upper boundary.

I wish to express my sincerest gratitude to Academician V. Fock for his participation in the discussion of certain above-mentioned questions.

N. KRYLOV.

[Received from Prof. J. Frenkel,

The Four-Colour Problem

THE correctness of the statement that any plane map may always be tinted with four colours in such a way that two areas meeting on the same boundary never have the same colour has always been admitted since Möbius mentioned it in 1840, although no mathematical proof of this theorem has yet been firmly established. I think I have found a rigorous and general proof of it. First, I have a theoretical proof of the common enunciation; secondly, I suggest a practical method of colouring. The complete paper is being submitted for publication elsewhere.

(1) Any plane map can be represented schematically as follows. Each area is figured by a point, and every contact between two contiguous areas is represented by a line connecting the figuring points. It is not difficult to show that any map, however complicated, can be reduced to a system of connected triangles externally limited by a unique triangle.

Then, using the method of general induction, I have shown that if it is always possible to colour a net of n vertices by means of four tints, the property remains true for a net of $n + 1$ vertices. In order to make this clear, I have used a theorem which is enunciated as follows : If a net R consisting entirely of triangles and of one—and one only—quadrilateral is colourable, then the net R^1 obtained by adding one supplementary diagonal in the quadrilateral is also colourable.

The evidence that a simple net consisting of a single triangle is colourable leads by induction to the complete demonstration.

(2) The foregoing statement is the basis on which the practical method of colouring rests.

A net already coloured with the four tints, 1, 2, 3, 4, might be coloured otherwise in black and white, making, for example, 1 and 2 white, and 3 and 4 black, in such a way that every polygonal black or white chain is open or when closed involves always an even number of vertices. The reciprocal proposition is true.

On the other hand, it is always possible to classify the vertices of any given net to be coloured in three groups, α, A, B, with two exceptional vertices, and to number the vertices: 1, 2, 3, . . . n, during the process of classification.

By definition, a vertex belonging to group α is directly connected with two and only two vertices, the number of either being lower than its own number. In the same way, a vertex A is connected with three, and a vertex B with four vertices. Nevertheless, it might happen that a vertex is connected with five preceding vertices, belonging then to a new type C. In this case, owing to a definite diagonal mutation of chosen sides of the net, such a vertex enters the group B.

All vertices being numbered and classified in types α, A, B, excepting the two vertices numbered 1 and 2, a general rule can be given for marking the vertices of the net in black and white in such way as to avoid any closed chain, black or white, involving an odd number of vertices.

After that the net can be coloured in the four tints 1, 2, 3, 4.

If any alteration has been made owing to eventual diagonal mutations, it is possible to return to the previous structure of the net, basing the necessary modifications of marking and colouring on the fundamental theorem enunciated in (1).

Bibliography. A short account of the history and bibliography is given in Rouse Ball's "Mathematical Recreations and Essays" (London: Macmillan and Co., Ltd., 1905, pp. 51–54), from which it appears that the problem was mentioned by Möbius in 1840 ; Francis Guthrie communicated it to De Morgan about 1850 ; although familiar to practical map-makers, Cayley redirected attention to it in 1878, but did not know of any rigorous proof of it ; in 1880 Tait published a solution (*Proc. Roy. Soc. Edinburgh*, **10**, 729 ; 1880) but it would seem to involve a fallacy (see J. Peterson, of Copenhagen : *L'Intermédiaire des Mathematiciens*, **5**, 225 ; 1898 ; **6**, 36 ; 1899).

Distribution of Nucleic Acids

A QUESTION of great interest has been raised by Gulland, Barker and Jordan when they object to a nucleic acid terminology proposed by us[1]. We suggested that the terms 'chromonucleic' and 'plasmonucleic acid' be used as synonyms for 'desoxyribose' and 'ribose nucleic acid' respectively[2]. The latter terms are useful because they clearly denote an essential difference in *chemical* composition of the two known types of nucleic acid ; the former terms would be useful because they describe the striking *biological* distribution of the two nucleic acids.

In recent years it has been shown, contrary to what had been believed previously, that both types of nucleic acid are present in both plant and animal cells. There is indeed a profound difference in the distribution of the two types of nucleic acid; but the difference is discernible within each plant and animal cell. In all plant and animal cells on which careful observations have been made, one type of nucleic acid has been detected in the chromatin only, and we have accordingly suggested the name 'chromonucleic acid' for this type. The other type of nucleic acid, 'plasmonucleic', occurs in the cytoplasm, in the plasmosome (nucleolus) and possibly in minute quantities in the chromatin[3,4]. The distribution of the two nucleic acids provides a biochemical basis for the now classical cytological distinction between chromatin and other constituents of the cell. 'Chromonucleic' and 'plasmonucleic acid' are terms that epitomize the point of view of the cyto-geneticist, much as the term ascorbic acid does the point of view of another group of biologists—better than does the chemical term 2,3-enediol-*l*-gulono-1,4-lactone ! Gulland, Barker and Jordan object to the terms we have suggested because nucleic acids are present in viruses and bacteria as well as in cells with clearly defined nuclei. 'Chromonucleic' and 'plasmonucleic' are terms based on a distribution of the two acids within cells in which certain morphological features are visible. The presence of nucleic acids in viruses and bacteria is regarded by Gulland, Barker and Jordan as an "exception" to this distribution. This, in our opinion, is altogether too narrow a view to take, and it becomes apparent at once when we consider the presence of 'chromonucleic (desoxyribose) nucleic acid' in bacteria.

The existence of nuclei in bacteria has been a moot question for years. In the nuclei of many animal and plant cells, chromatin forms by far the bulk of the nuclear substance, and in some nuclei more than 90 per cent of the chromatin consists of desoxyribose nucleoprotein (chromonucleoprotein)[5]. The presence of desoxyribose nucleic acid in bacteria[6,7] and the preparation from bacteria of a desoxyribose nucleoprotein strikingly similar to those prepared from all nuclei[5] indicates that the chemical equivalent of chromatin is present in bacteria ; and whether or not this chromatin is organized in a morphologically distinct nucleus becomes, in a sense, a secondary matter. The discovery that a chromonucleoprotein, like that present in the nuclei and not in the cytoplasm of animal and plant cells, and forming the bulk of their chromatin, also exists in bacteria, is surely not so much an exception to the statement that such nucleoproteins exist in the nuclei of cells of higher animals and plants as an indication that bacteria contain chromatin.

It appears fruitful at present to compare the viruses with the self-duplicating bodies known to be present within the cells of plants and animals. Some viruses (vaccinia, bacteriophage) contain desoxyribose nucleic acid ; others (the tobacco mosaic virus, for example) contain ribose nucleic acid[3]. The suggestion arises at once that some viruses may be related to those self-duplicating bodies, the genes, that are so closely associated with the chromonucleoproteins (desoxyribose nucleoproteins) of chromatin and that other viruses may be related to self-duplicating bodies in the cytoplasm, such as the chloroplasts, which contain plasmonucleoproteins (ribose nucleoproteins).

The nucleic acid terminology which we have proposed does not ignore the presence of nucleic acids in bacteria and viruses ; on the contrary, this terminology implies that the distribution of nucleic acids has a profound biological significance.

Carbonic Anhydrase

IN a recent letter in NATURE[1], Keilin and Mann question the zinc content of carbonic anhydrase reported by us. The facts seem to be that they have obtained an enzyme preparation (which they believe is highly purified) having a zinc content of 0·3–0·33 per cent[2], and we have obtained a preparation (which we likewise feel we have shown to be highly purified) having a zinc content of 0·2–0·23 per cent[3]. Realizing that criticism can be directed against the determination of any low zinc content, whether the method used be the dithizone method employed by Keilin and Mann or the method of Sahyun and Feldkamp used by us, we conducted preliminary experiments and reported[4] that "Before zinc estimations were conducted on the enzyme, analyses were made on a sample of zinc-insulin crystals with the same technique as was used in estimating the zinc in the enzyme. Duplicate results agree within 4 per cent. Moreover, these results were in good agreement with the metal content of the crystals as calculated from ash determinations. Along with each estimation of the zinc content of an unknown sample it was routine procedure to determine likewise the zinc content of a standard zinc solution". In all our estimations of the zinc content of the enzyme preparations, care was taken that a reasonable quantity of material was used. Recently Prof. Thode of McMaster University made polarographic determinations of the zinc content of our enzyme preparation and found it to be 0·22 per cent. We feel that the comparatively low zinc values reported by us are not attributable to the method of determination used in our work.

Keilin and Mann direct attention to the fact that the carbonic anhydrase content of ox blood as determined in our laboratory[5] was approximately twice that reported by them for washed ox red blood

corpuscles[2]. In view of the fact that "in any one species there is a two- to four-fold variation or more"[6] in the enzyme content of blood, it could be expected that there might be a difference in the enzyme values reported from the two laboratories. However, the primary object of our communication[5] was to direct attention to the marked instability of dilute solutions of highly purified preparations of the enzyme. This instability is so great that we believe it is impossible to determine accurately the potency of dilute aqueous solutions of the enzyme by the unmodified glass boat method used by Keilin and Mann. Our work showed that the addition of a very small amount of peptone or of certain other substances (themselves free from enzyme activity) rendered solutions of carbonic anhydrase stable and made assay possible. Such stabilized solutions of the purified enzyme had activity double that obtained for similar aqueous solutions of the enzyme when attempts were made to assay these immediately after the solutions were prepared for assay. It would be a matter of interest to determine the potency of the highly active preparation of Keilin and Mann in the presence of a small amount of peptone, to ascertain whether under these stable conditions their preparation would indicate an activity as great as that which we have reported.

Keilin and Mann state that the crystalline compounds of carbonic anhydrase with piperidine, *iso*-amylamine and *n*-amylamine described by us have "no relationship to the enzyme". Evidently they have not understood our use of these compounds. Of course these *dried* crystalline preparations are "devoid of catalytic activity", as are the dried crystalline preparations of the enzyme obtained from ammoniacal acetone and as are dried crystalline preparations of certain other enzymes. In the case of the hormone insulin, the crystalline base-insulin preparation *retains* activity after drying[3,7] even though the potency of insulin is ordinarily readily destroyed in the presence of a base. Since a substance so labile as insulin retains potency under these conditions, it seems that an explanation other than alkalinity must be found for loss in potency during drying of a crystalline preparation of a substance so remarkably stable to base (*p*H 12) as is carbonic anhydrase[6]. If consideration is given to the drying of the crystals, it seems not unlikely that water may be concerned. This is further suggested by the marked instability of the enzyme in dilute aqueous solutions, and by the fact that crystalline preparations of the enzyme obtained from ammoniacal acetone are inactive after drying.

Keilin and Mann also object to the use of these liquid bases because they form crystalline compounds with other proteins. As a matter of fact, there are few chemicals which are specific for the crystallization of only one protein. It was a matter of much interest to us to learn that Keilin and Mann had often observed thin plates during precipitation of the purified enzyme.

Antibacterial Action of Arsenic

Voegtlin[1] and Eagle[2] have produced convincing, even if partly circumstantial, evidence that organic arsenicals act on trypanosomes and spirochætes by combining with –SH (thiol) groups in enzyme systems essential for the metabolism of these organisms. These workers showed that arsenobenzenes act in this way only after oxidation to the corresponding arsenoxides, and likewise pentavalent arsenicals become active only after reduction to their arsenoxides.

More recently, Fildes[3] has produced evidence that mercurial antiseptics acted on bacteria by combining with –SH groups in enzymes essential for bacterial metabolism. Accordingly one of us (J. E. F.) pointed out[4] that arsenoxides should act as antiseptics towards a wide range of bacteria, as mercurials do. Should arsenoxides prove ineffective against a variety of bacteria *in vitro*, a vital inconsistency between the Voegtlin theory of the action of arsenicals on trypanosomes and spirochætes and the Fildes theory of the action of mercurials as antiseptics would be revealed.

Curiously enough, no reference earlier than 1942 to the successful action of arsenicals in significant dilution against common pathogenic bacteria (that is, other than the atypical spirochætes and bartonellæ) could be found. Hirsch[5] showed that atoxyl (*p*-aminophenylarsonic acid) has a sulphonamide-like action on *B. coli*. But here it is not acting as an arsenical but through its structural resemblance to *p*-aminobenzoic acid. Indeed Peters[6] has shown that other pentavalent arsenicals not having this resemblance, such as acetarsol (*p*-hydroxy-*m*-acetylaminophenylarsonic acid) and tryparsamide (N-phenylglycineamide-*p*-arsonic acid), are inactive towards this organism. Peters noted, however, that *m*-amino-*p*-hydroxyphenyl-arsenoxide was highly active against *B. coli* and was not antagonized by *p*-aminobenzoic acid. Osgood[7] had shown that neoarsphenamine (an arsenobenzene) was effective against *Streptococcus viridans* in bone-marrow culture if left for 2–3 days, but believed that the mechanism was different in this case from that obtaining with trypanosomes.

To assist the clarification of this rather confused picture, we have submitted arsenical drugs typical of each of the three possible levels of oxidation to a bacteriostatic analysis. The technique followed has been previously described[8], and the same pathogenic strains were used as heretofore. The medium used has been found to contain enough *p*-aminobenzoic acid completely to counter any sulphanilamide-like drug activity. The arsenoxide was used in the form of 'Mapharsen N.N.R.' (synonyms: 'Mapharside', 'Neohalarsine', arsphenoxide), due allowance being made for the diluent present. The acetarsol was dissolved in an equivalent of sodium hydroxide, the proflavine in an equivalent of hydrochloric acid and the other substances in water. The results are given in the accompanying table.

Discussion. The table demonstrates that arsenoxide behaves towards a wide range of bacteria as a potent antibacterial of the same order of activity as the acridines and the mercurials, and it is as easily inactivated by a typical thiol compound as mercurials are. The pentavalent arsenical (acetarsol) was quite inactive and the arsenobenzene (neoarsphenamine), which was tested under hydrogen to secure conditions unfavourable to its oxidation, showed only slight and limited activity.

It is concluded that at least one organic arsenical

at the arsenoxide level of oxidation is a potent antibacterial acting after the fashion of the mercurials, whereas closely related arsenicals at both higher and lower levels of oxidation are inactive. Hence the Voegtlin and the Fildes hypotheses are more closely linked than heretofore. This hitherto unsuspected antistaphylococcal action of arsenoxide is, in our experience, inferior only to that of penicillin, ethyl mercurithiosalicylate ('Merthiolate') and crystal violet. In view of the widespread experience of the use of this drug in syphilis, it should not be a difficult matter to determine whether it is clinically useful in staphylococcal infections.

We wish to thank Miss J. Stone for valuable assistance in performing these tests.

Cataphoretic Velocities of Pure Copper Ferrocyanide Sol

The cataphoretic velocities of the sols formed from the precipitates from potassium ferrocyanide and copper sulphate solutions peptized with water after washing by centrifugalization were measured by the microcataphoretic method[1].

In the pure sol of copper ferrocyanide, the cataphoretic velocities of particles of different sizes vary from $-16 \cdot 5 \times 10^{-5}$ to $-56 \cdot 8 \times 10^{-5}$ cm. per sec. per volt/cm. It is found that the larger particles move with a higher velocity and smaller particles with a lower velocity. Therefore the velocity we actually get after calculation is the average of all the velocities of all the particles.

The cataphoretic velocities of centrifuged sols are less than those of the non-centrifuged sols[2]. The cataphoretic velocities of a sol increase with time. If the non-centrifuged sol be kept for a month and then centrifuged, it is found that the centrifuged sol has a higher velocity than the non-centrifuged sol.

A Method for Collecting Sporozoites of *Plasmodium gallinaceum* by Feeding Infected *Aedes aegypti* through Animal Membranes

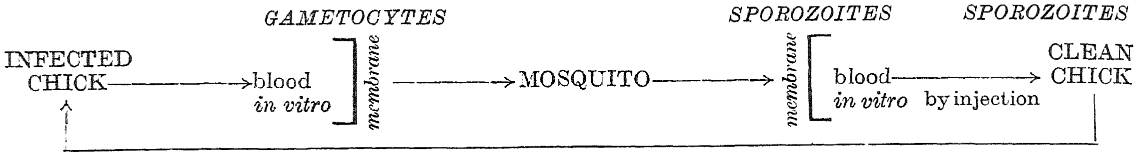
The well-known difference between the resistance of blood-inoculated and mosquito-induced malaria indicates that sporozoites, or the stages arising immediately from them, are very resistant to the action of the known anti-malarial drugs. Since a true prophylactic drug, that is, one which will prevent sporozoite-induced infections, is the most urgent requirement in the chemotherapy of malaria, a method for testing drugs directly on sporozoites is of great importance. Hitherto the only method of doing this was to obtain sporozoites by the dissection of salivary glands from infected mosquitoes, which is both laborious and unsatisfactory, as the sporozoites are always mixed with and may be protected by fragments of the salivary gland cells. Thus it is difficult to obtain them in uniform suspension and to be sure that they are all exposed equally to the action of the admixed drugs being tested.

In order to overcome these difficulties, we began to work upon the possibility of obtaining sporozoites free from gland tissue by feeding infected mosquitoes (*Aedes œgypti*) through animal membranes. Gordon[1] had shown that mosquitoes would feed through a fresh animal membrane, and Yoeli[2] had infected *Anopheles elutus* with *Plasmodium falciparum* by inducing the mosquitoes to gorge upon infected blood through a prepared rabbit-skin membrane.

The type of membrane which we have found to be the most successful is one made of chicken skin. We prepared it by soaking the skin of a 1–3 week old chick in absolute alcohol for at least 30 minutes, washing it in running tap water and stretching it over a piece of glass tubing 2·5 cm. × 6 cm., and keeping it in place, until dry, by a thin rubber band. On drying, the skin is thin and parchment-like and adheres firmly round the glass tubing, making a water-tight seal.

The highest rates of gorging are obtained when the blood in the membrane (1·5–3 c.c. of heparinized chick blood) is warmed to 41–42° C. and kept warm by a surrounding water-jacket filled with water at that temperature. Moistening the outer side of the membrane, that is, that presented to the mosquitoes, with saliva also increases the rate of gorging as compared with a dry surface. The apparatus is placed upon the mosquito-netted top of a jar containing *Aedes œgypti* so that the surface of the membrane rests upon the netting. Gorging is effected in the dark in an incubator at 28° C., in a moist atmosphere.

We have infected *Aedes œgypti* with *Plasmodium gallinaceum* by feeding mosquitoes through a mem-



INFECTIVE CYCLE OF *Plasmodium gallinaceum*, BY *Aedes ægypti*, THROUGH ANIMAL MEMBRANES.

brane upon heparinized chick blood heavily infected with gametocytes. The rate and intensity of infection, as assessed by oocyst counts on the fourth day, were equal to those obtained from mosquitoes of the same age-group gorged on the same chicken immediately prior to drawing the blood for the membrane experiment.

What is, however, more important for our work, is that we have been able to demonstrate that infected mosquitoes, when they gorge through a membrane, extrude sporozoites into the blood, and that these sporozoites are viable, since the blood containing them when injected into clean young chicks produces infections typical of mosquito transmission.

Mosquitoes, which became infected as a result of gorging through a membrane upon blood containing gametocytes of *P. gallinaceum*, have ejected sporozoites through a membrane into uninfected chick blood, and this blood has proved infective when injected into a clean chick. The cycle of development as shown in the accompanying chart has, therefore, been completed.

In obtaining sporozoites from infected *Aedes ægypti* only batches of mosquitoes which have been proved, by oocyst count on the fourth–fifth day, to be heavily infected are used. The rate of gorging through a membrane of infected mosquitoes (that is, mosquitoes which had already had one, the infective, blood-meal) is generally not so high as when mosquitoes gorge for the first time, but usually at least 50 per cent gorge, and in certain batches the rate has been as high as 90 per cent.

Our practice is to allow the mosquitoes thirty minutes in which to gorge upon 1·5–3 c.c. of heparinized blood from clean chicks, and then to pipette out the blood from the membrane and shake it well to ensure that the sporozoites are evenly distributed. The blood (0·4–0·5 c.c. per bird) is injected intravenously into 5–10 day old chicks. Groups of three or four chicks injected with blood from membranes through which batches of 35–53 mosquitoes had gorged showed parasites in their peripheral blood on the sixth–seventh day. This incubation period is, in our experience, similar to that in chicks bitten by two to four heavily infected mosquitoes. In one experiment, blood from which forty-five mosquitoes had gorged produced infections of such intensity in six chicks that five died on the seventh day, post-mortem examination revealing enormous numbers of exoerythrocytic schizonts in the capillaries of the brain.

Infected Aedes remain infective after gorging through a membrane and can be induced to eject their sporozoites by this method on more than one occasion. Thus a batch of thirty-nine infected mosquitoes ejected sporozoites through a membrane into clean blood on the ninth day after infection. From this blood five chicks were infected. Six days later, the twenty-one Aedes surviving gorged again through a membrane upon clean blood, and the blood in the membrane proved infective to the two chicks inoculated with it, parasites being found in the peripheral blood of each chick on the sixth day.

Experiments are now being made upon the applicability of this method for testing the action of anti-malarial drugs directly upon sporozoites and the developmental stages arising from them, and the results will be reported later.

Action of Inert Dusts on Insects

IN his recent letter Dr. Wigglesworth[1] has explained the desiccating action of inert dusts on insects by the abrasion and perhaps adsorption of waxy substances forming a thin layer on the cuticle. The following results, which appear to confirm his conclusions, were obtained while comparing the dust resistances of various races and species of Drosophila, and spraying dust on some other animals. Of the various dusts tested, the loss of water was most accelerated by shaking the insects with charcoal of plant or animal origin. At 25° C. and 40–50 per cent relative humidity, *Drosophila melanogaster* flies were dead after eleven minutes, and *D. subobscura* after nine minutes, whereas in an atmosphere saturated with moisture, they survived for many hours. Mosquitoes, house-flies and house-spiders dusted with charcoal and kept in a centrally heated room died in less than an hour, and a young newt died in about two hours. Earthworms and slugs, on the other hand, were not killed by the dusts.

Pupæ of *D. melanogaster* did not die in charcoal, but the flies emerging from them soon did; larvæ survived for several hours. Drosophila flies which were narcotized in carbon dioxide, shaken and kept with charcoal in an atmosphere sufficiently rich in carbon dioxide to keep them immobilized, survived in this condition for several hours, and died only ten minutes after they had recovered in air and had been running. Similarly, at 5° C. and about 70 per cent relative humidity, Drosophila flies survived in charcoal for several hours. If immobilized by carbon dioxide or chill after they had been crawling in charcoal for two to three minutes, Drosophila flies dried up and did not recover.

The dependence of the desiccating effect on movement was also evident in the first instars of Dixippus. Cataleptic individuals survived much longer when dusted with charcoal than did active animals. In the cottonstainer Dysdercus sp., the abrasive effect of charcoal could be observed directly under the binocular microscope without using a dye. If a later instar of this bug was dusted with charcoal and turned on its back, white scratches, looking as if paraffin

wax were scratched with a needle, could be observed on the cuticle of the abdomen where the femora had rubbed it. If the legs were cut before dusting, no scratching could of course occur, and the nymph survived much longer.

A System of Notation for Petroleum Hydrocarbons

I SHOULD like to invite attention to a system of notation I am using for petroleum hydrocarbons. In recent years the tendency to invent trade names (such as 'triptane' for 2,2,3-trimethyl butane) is understandable, but is to be deplored as a retrograde step away from unification and systematization. There is no need to depart from the international system of nomenclature if some simple system of notation is used for groups of atoms. The accompanying table contains a list which I have found suitable. It applies generally to hydrocarbons boiling in the gasoline range and a few simple substituted derivatives.

NOTATION FOR THE SYSTEMATIC NAMES OF HYDROCARBONS.

Abbreviation	Group or meaning	Abbreviation	Group or meaning
M	methyl	X	xylenes
E	ethyl	i	*iso-*
P	propyl	s	secondary
Ph	phenyl	t	tertiary
b	butyl	c	cyclo
a	amyl	Δ	double bonds (positions indicated by following figures)
4	butane		
5	pentane		
6	hexane	δ	triple bonds (positions indicated by following figures)
7	heptane		
8	octane		
9	nonane		
10	decane	Substituents	
B	benzene	F	fluoro
T	toluene	C	chloro
oX	*o*-xylene	Br	bromo
mX	*m*-xylene	I	iodo
pX	*p*-xylene	N	nitro
		A	amino

Only the necessary minimum number of symbols is used, as there is no need to include the total number of alkyl groups in the name. For example, 2,2,3-trimethylpentane becomes 223M5; *iso*-octane is written i8, and 2,2,4-trimethylpentane becomes 224M5. *Iso*-pentane can be written i5, though the purist would prefer 22M3. In the naphthene series *cyclo*pentane becomes c5, and 1-methyl-3-*iso*propyl *cyclo*hexane becomes 1M3iPc6. Among the aromatic hydrocarbons we have EB for ethyl benzene and 135MB for mesitylene. The olefine butadiene becomes 4Δ13 and 2-methyl-3-ethyl pentadiene Δ2–4 becomes 2M3E5Δ24. Acetylene is 2δ. I have no experience of using this notation for the substituted hydrocarbons, and the extension to the list is offered without experience to stimulate criticism or extension of the notation.

Similar notations are probably in use in other laboratories, but in these days when the detailed analysis of fuels is occupying so many chemists on both sides of the Atlantic, a simple, uniform notation for the international nomenclature for labelling samples and for use on graph or in tables would be of considerable value, particularly as so much of this information has to be exchanged.

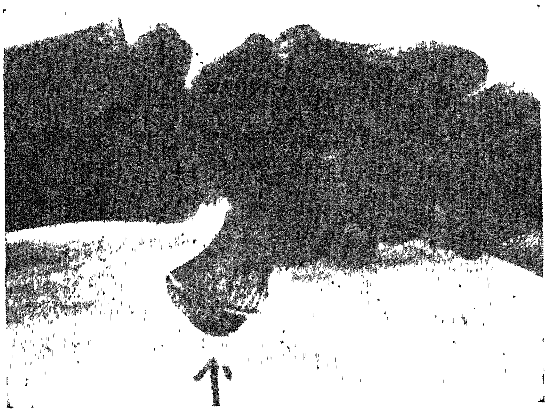
The Pisiform Bone

THE pisiform bone is often dismissed by the human anatomist as an insignificant sesamoid bone in the tendon of the flexor carpi ulnaris muscle. notwithstanding its articulation with the os triquetrum (os ulnare of comparative anatomy).

An extensive analysis of radiographs of the carpus in various mammals has shown that this minisculum is a canonical carpal bone, for in all young primates examined, with the exception of man, it presents a secondary bony centre with a well-marked epiphysial growth cartilage. The bony epiphysis is clearly shown in the accompanying lateral radiograph of the wrist of a young *Macacus rhesus*.



LATERAL RADIOGRAPH OF THE WRIST OF A YOUNG *Macacus rhesus*. (× 3.) THE ARROW POINTS TO THE BONY EPIPHYSIS OF THE PISIFORM BONE.

The pisiform is now, for the first time, shown to be analogous to the os calcis, which alone among the bones of the tarsus has a secondary centre of ossification in all primates, including man.

The hitherto unsuspected existence of this epiphysis in the pisiform bone makes it necessary to revise for all vertebrate forms the present views on the morphology of the carpus and tarsus. No mention of the epiphysis is found in the book on the hand by Wood Jones[1], in the anatomy of the rhesus monkey by Hartman and Straus[2], or in the extensive monographs by Schreiber[3] and Schwartz[4]. The same is true of the various papers by Broom and Watson on fossil forms.

Geostatics

RECENTLY, at King's College, Newcastle upon Tyne, more than seventy engineers and architects studied the subject of 'soil mechanics'. A week of lectures and drawing office practice under the direction of Mr. A. W. Skempton, of the Building Research Station, resulted in considerable discussion of the various aspects of the problems involved. In such discussions, the name given to this rapidly developing science was the subject of criticism on the following lines:

(1) The word 'soil' has, for centuries, signified that extreme upper layer of the earth's crust which can support plant life. In 'soil mechanics' the word is forced out of its usual connotation to include any of the unconsolidated or partially consolidated geological sediments existing to any depth likely to be of interest to the engineer or architect.

(2) Even if the meaning of 'soil' be extended to include sands, gravels, silts, and clays of any depth, it cannot, logically, be applied to harder materials such as shales, to which the methods of 'soil mechanics' do apply.

(3) The term 'mechanics' is misleading and covers a field which is too wide to identify the specialized statical problems involved. The methods of 'soil mechanics' are not, for example, extended to include dynamical problems.

(4) The term 'soil mechanics' is clumsy, and not self-explanatory.

'Soil mechanics' is the science of applying the methods of statics to data deduced from the measured properties of geological sediments. The results obtained indicate the static forces involved in earthworks or in foundation design. For this reason, and since there is no collective term to indicate the loose sediments of the earth's crust, we suggest that the term 'Geostatics' should be employed. This suggestion forms a constructive reply to the well-founded criticisms of the present name, and covers adequately and neatly all possible aspects of 'soil mechanics'.

Wordsworth and Science

THE important question is surely not whether Wordsworth should now and again have scoffed at men of science with or without provocation, but whether the poems as a whole suggest that he felt at heart that it were incumbent upon poets to give recognition to scientific knowledge. Now I submit and, indeed, tried to show in an article published in NATURE of November 28, 1942, that the very strength of Wordsworth's unique Nature mysticism depends on the tacit acceptance of science in principle discernible in the poems. This must be precisely why the forerunners of this journal so wisely selected a now time-honoured Wordsworthian motto, and why ever to discard it would be a most foolish blunder.

I should like to quote a few lines from "The Excursion" as exemplifying with peculiarly solemn power the depth of this great poet's philosophical outlook upon Nature:

"He, many an evening, to his distant home
In solitude returning, saw the hills
Grow larger in the darkness; all alone
Beheld the stars come out above his head,
And travelled through the wood, with no one near
To whom he might confess the things he saw."

That lad returning from school over the wild Perthshire hills shows himself a "visionary of the first water"—of the finest calibre with the making both of a man of science and a poet; for he is seeking to peer behind the natural scene and to capture a hidden meaning in the grand and impressive phenomena of the landscape. Here we certainly have flights of poetical imagination properly disciplined by scientific caution and faith in the "solid ground of nature". Such great moments as were vouchsafed to the Wanderer will repeatedly and often unexpectedly come to everybody who cultivates the requisite outlook.

Patent Law and Procedure in Austria

IN view of the present interest in the reform of the patent law and procedure in Great Britain (see NATURE, May 6, p. 553), it may be worth while to refer briefly to the manner in which the Austrian Patent Act, 1925, has tried to cope with one of the most intricate problems concerned, namely, the treatment of the scientific worker in his quality as inventor. Under this Act—which seems to be the most progressive legislation in this field of law—the employee is considered the owner of his inventions, even if they had been made in the course of his employment. He may assign his invention and the patent applied or granted therefor to his employer or may grant him a licence, and is bound to do so if agreed upon in either an individual or collective agreement; but he is entitled to claim an adequate compensation for such assignment or grant of licence, a right which he cannot validly waive in advance. Failing an agreement between employer and employee, the Court has to assess the compensation, taking into consideration the importance of the invention, the possibilities of utilizing the same and the part which facilities provided by the employer and his experience have played in arriving at the invention. Such a decision may be altered by the Court on application of either side if circumstances have essentially changed.

Experience has shown in Austria that the question of compensation has nearly always been solved by agreement, so that resort to the Court was necessary only in very few exceptional cases.

Petrological Microscopes

A SMALL committee has been formed, including representatives of the Mineralogical and Geological Societies, with the object of furthering the manufacture of petrological microscopes in Great Britain. The committee would welcome comments from any persons interested with whom they are not already in touch, to be addressed to the Secretary, Petrological Microscope Committee, Geological Survey Office, Exhibition Road, S.W.7.

Putrescine in the Biosynthesis of Hyoscyamine

IN plants of *Atropa belladonna* and *Datura stramonium*, growing normally, hyoscyamine appears to be formed principally in the root, with putrescine as an intermediate metabolite, and then moves upwards through the vessels into the stem, leaves, fruit and seeds (B. T. Cromwell, *Biochem. J.*, **37**, 717 and 722; 1943). The author's previous work on the biosynthesis of berberine and hyoscyamine had led to the conclusion that these alkaloids are synthesized from products of carbohydrate and protein breakdown. Work on the nature of the intermediate reactions leading to the formation of hyoscyamine, by experiments on exudates of cut stems, grafting and slow injections of various substances into stem stumps or branches of *Atropa belladonna* and *Datura stramonium*, showed the root as the probable locus of synthesis, and demonstrated the stimulating effect of arginine, hexamine, formamol and especially putrescine. This is compared with results of other workers (for example, Dawson. *Science*, **94**, 396; 1941), who concluded that nicotine is synthesized mainly in the root of the tobacco plant and that the alkaloid moves from the root system via the xylem to the leaves. It was of interest to determine the manner in which putrescine provided its contribution to the hyoscyamine molecule. Bearing in mind the use of succinaldehyde in the synthesis of tropinone, it might be concluded that putrescine gives rise to succinaldehyde by oxidation. The occurrence of an enzyme system bringing about the oxidative deamination of putrescine with formation of ammonia and an aldehyde in roots and etiolated shoots, and the isolation of small amounts of putrescine from leaves and upper stems of *Atropa belladonna* and *Datura stramonium*, add weight to these considerations.

Biology of the Albacore

VERNON E. BROCK has discussed ("Contribution to the Biology of the Albacore (*Germo alalunga*) of the Oregon Coast and other Parts of the North Pacific". *Stanford Ichthyological Bulletin*, 2, No. 6; Dec. 1943. Contrib. No. 10, Department of Research, Fish. Commission of Oregon) the albacore fishery in connexion with the probable causes of the sudden reduction in abundance off the coasts of California. This is the result of the first four years study and describes certain biological features in the albacore populations of the Pacific coast with emphasis on those of Oregon, and presents a review of all available material on the species from other parts of the North Pacific in so far as the material bears on the fishery problems. Fish with ripening ova are not present in the Oregon fishery and have never been recorded from the Californian fishery. It is probable that those forming the fishery have never spawned. The available evidence strongly suggests that only a few year-classes are present in the temperate-water fisheries for this species and that these are immature. This may, at least in part, account for the history of instability shown by the Californian fishery and may cause a similar instability in the Oregon fishery. The populations exploited by the North Pacific albacore fisheries may represent three different stocks or races which centre off the coasts of North America, Hawaii and Japan. The existence of albacore in mid-Pacific at positions roughly midway between these localities makes it appear possible that a certain amount of mingling may occur. It is not known if those fish occurring offshore represent wholesale migratory movements, but if so, the study and conservation of this species would cover the entire North Pacific Basin.

Mutations in Bacteria

THE nature of variation in bacteria is a theme upon which disagreement exists. G. Luria and M. Delbruck (*Genetics*, 28, 491; 1943) have discovered some important facts regarding this problem. *Escherichia coli* B. in culture with bacterial virus 9 first shows complete lysis and then, after a few hours, secondary cultures make their appearance. These consist of cells which breed true to resistance to attack by the virus. The distribution of resistant bacteria in the various cultures of sensitive bacteria was ascertained. The fluctuation in the number of resistant bacteria was considerably higher than could be accounted for by sampling error. On the theory that the resistance is due to acquired immunity, there will either be a binomial distribution or a Poisson series if the numbers are small. On the mutation theory the assumption is that there is a fixed chance of change per unit time, which is measured in cycles of bacterial division. The authors show that a variance much greater than unity is to be expected. In every case, the experimental results accord with the calculations on this theory, with a discrepancy of even higher variability than expected. The mutation-rate was determined experimentally to be $2{\cdot}45 \times 10^{-8}$ per bacterium per division cycle.

New Species of Aquatic Fungi

Two papers recently published by C. F. Ingold (*Trans. Brit. Mycol. Soc.*, 26, Pts. 3 and 4, 104 and 148; Dec. 1943) describe four new species of aquatic Hyphomycetes. *Dendrospora erecta* and *Piricularia anomalum* were found on decaying submerged oak leaves. The former species necessitated also the creation of the new genus Dendrospora, the main criterion of which is the production of tree-like spores, as the name implies. *Tricladium anomalum* was found growing on decaying submerged leaves of *Typha latifolia*, while *Triscelophorus monosporus* inhabited leaves at a later stage of decay, too rotted for identification. Triscelophorus is also a new genus. It seems possible that aquatic Hyphomycetes are of fairly wide distribution. Dr. Ingold has recorded several species upon decaying sweet chestnut and hawthorn leaves in addition to oak and alder leaves as described in an earlier paper.

Continental Drift and Fossil Floras

IN a study entitled "Continental Drift and Plant Distribution" (privately printed, 1943), Prof. D. H. Campbell, of Stanford University, California, argues that, from a comparison of the existing and fossil floras of the northern and southern hemispheres, it is clear that the two areas were completely separated up to the end of the Mesozoic period, and that North America and Eurasia have always been more or less intimately connected. The relations between the genera and even species of New Zealand and Chile, and West Africa and Brazil, are so close that former land connexions must be assumed. Most of the common forms could not have been transported by ocean or air currents. The almost complete absence from the southern continent of the characteristic

boreal trees, such as Pinaceæ, Fagaceæ, Salicaceæ, Magnoliaceæ and others, and the absence in the northern hemisphere of many austral families, like the Myrtaceæ and Proteaceæ and the coniferous Araucaria and Podocarpus, is evidence of the complete separation of boreal and austral land masses from late Palæozoic to late Mesozoic times, and confirms Du Toit's theory of two original land masses of Laurasia and Gondwana rather than Wegener's theory of Pangæa. When the first connexions between the two were established is not certain. The paper contains a great deal of closely reasoned evidence.

Meteorites and an Earth-Model

UNDER this title R. A. Daly discusses the old hypothesis that the materials of the substratum and core of the earth are likely to be closely similar to those of average meteorites (*Bull. Geol. Soc. Amer.*, **54**, 401; 1943). The paper summarizes the principal observed facts about the nature of meteoritic stones and irons, and the reasons for supposing them to be fragments of a disrupted parental planet. After comparison between the latter and the earth itself, the hypothetical evolution of the earth is tested by reference to the terrestrial discontinuities revealed by seismic evidence, and to mean density, moment of inertia, radioactivity and plasticity. Rough estimates of the temperatures and the degrees of strength of the materials in depth are deduced. The author assumes the earth to have been initially gaseous with a temperature well above the boiling point of iron (about 3,000° C.) and traces the probable effects of condensation and differentiation. The suggested course of development leads to an earth-model which has the following succession from surface to centre: a crust or lithosphere; a thicker vitreous asthenospheric (weak) shell; a still thicker crystallized mesospheric shell; and a nickel-iron core, probably fluid and possibly behaving much like a gas. It is frankly confessed that the processes envisaged fail to account satisfactorily for the existence of a sharply defined radioactive layer. Moreover, no attempt is made to apply tests of a dynamical character, that is, to confront the model with the geological facts of mountain-building and vulcanism. Nevertheless, quite apart from its conclusions, some of which are necessarily highly speculative, the paper is extremely valuable as a compendium of all the relevant data by which such speculations must be guided.

Reaction Kinetics in Solution

IN the Tilden Lecture to the Chemical Society (*J. Chem. Soc.*, 629; 1943) R. P. Bell gave an account of some attempts to calculate velocity coefficients on the basis of activation energy. The fundamental equation was proposed by Arrhenius, and for bimolecular reactions is $k = Ae^{-E/RT}$, where E is the activation energy, having values from 7 to 40 k.cal. per mol. The values of A vary considerably ($10^2 - 10^{19}$) and, although the values are distributed over the whole range, smaller values apply to reactions between uncharged molecules and larger values to reactions between ions. The A values have been interpreted either as giving the product of the collision frequency Z and a so-called probability factor P, namely, $A = ZP$, and also on what is called a transition state theory, in which the equilibrium constant K for a state X through which the reacting molecules pass during reaction ($A + B \rightleftharpoons X$) and the thermal velocity v, which does not vary greatly from one reaction to another, are connected by the equation $k = Kv$. It appears that in solution Z is not greater than four times its value for the reaction in the gaseous state. The question of solvation is an important one, and is dealt with rather fully in the lecture. In a series of solvents A and E are found to change in a parallel manner. The lecture gives a concise yet comprehensive survey of the subject with which it deals.

Boundary Lubrication and Heat of Absorption

FOLLOWING an earlier investigation of the effect of temperature on the boundary lubrication of mild steel surfaces by a number of pure long-chain compounds, J. J. Frewing has now published a study correlating the results with heat of absorption (*Proc. Roy. Soc.*, A, **182**, 270; 1944). The frictional behaviour between mild steel surfaces lubricated with solutions in white oil of long-chain halides and other compounds was studied under high loads at low speeds. For all compounds a transition from smooth sliding to stick-slips occurs at a temperature characteristic of the particular solution used. The transition temperature increases with the concentration. Each solution builds up, and is in equilibrium with, an absorbed and oriented film of the polar compound on the surface. By assuming that the transition occurs when the surface concentration of this film decreases to a certain value which, for any one material, is independent of temperature, an equation was deduced relating the concentration and transition temperature with the heat of absorption (U). The equation fits the experimental results well. From the values of U it appears that these long-chain polar compounds are adsorbed by the interaction of their dipoles with the atoms in the metal surface and not by any chemical reaction. The results also suggest that the esters are similarly oriented at metal and at aqueous surfaces.

Polarization in Fraunhofer Lines at the Sun's Limb

DR. ZANSTRA showed in 1941 that if atoms in the solar atmosphere acted like classical oscillators, light within Fraunhofer lines should be polarized near the sun's limb (*Mon. Not. Roy. Astro. Soc.*, **101**; 1941). R. O. Redman examined the solar spectrum at $\sin\theta = 0{\cdot}985$, and was able to obtain only a small amount of polarization in the line 4227, Ca I, the observed effect being only about one tenth of that predicted by theory. Zanstra showed later that collision damping would reduce the predicted polarization very considerably, and Redman has suggested recently that the polarization would be weakened by the roughness of the sun's surface (*Mon. Not. Roy. Astro. Soc.*, **103**, 173; 1943). Fresh observations have now been made by Redman at the Radcliffe Observatory, using an improved method (*Mon. Not. Roy. Astro. Soc.*, **103**, 6; 1943). A description of the apparatus is given. By suitable arrangements the observations are much more accurate than those previously obtained. In addition to certain precautions, check photographs were made at the centre of the sun's disk, where there should be no polarization, these being taken immediately after the limb photographs. The results confirm the previous conclusion that polarization in the Fraunhofer lines is much smaller than was predicted by Zanstra's original theory.

PHOTOGRAPHY IN AGRICULTURAL RESEARCH

ON April 29, the Association for Scientific Photography held a meeting at Caxton Hall, London, to discuss "Photography as a Tool in Agricultural Research". Papers were read by Dr. E. M. Crook and Mr. V. Stansfield, of Rothamsted Experimental Station, and by Mr. J. C. Hawkins and Mr. R. H. Broome, of the National Institute of Agricultural Engineering, Askham Bryan, and illustrated by lantern slides and cine films.

The word 'tool' was included in the title in order to emphasize the fact that the centre of interest should be no radically new departure in the use of photographic materials in agricultural research, but simply the day-to-day use of well-known and well-tested techniques such as can be depended upon to yield results with a minimum of trouble and incidental research.

A large proportion of the photographic work of both institutes, as indeed is true of all photography applied to science, arises as a result of the need for an adequate means of preserving a detailed and easily comprehended record of very complex situations and phenomena. A single photograph will often record experimental results more adequately than several pages of written notes; in addition, it often preserves for future reference effects which were quite unnoticed at the time the experiment was made. Similar considerations apply to the use of photographs for passing on instructions for assembling or adjusting an agricultural implement or recognizing a certain plant disease. The photographic record, being objective, is also a valuable means of establishing beyond dispute the results of tests such as the Institute of Agricultural Engineering continually carries out on articles submitted by manufacturers.

Many records are enhanced in value, and in dramatic effect, by the use of colour. This is especially true of the recording of plant disease symptoms and the results of manurial trials such as make up a considerable proportion of the work at Rothamsted. On the other hand, where relative positions and the demonstration of movements are important, as at Askham Bryan, colour does not present any particular advantage. Other special techniques include the use of infra-red plates to record satisfactorily the lesions in the streak diseases of potato.

Recording does not, of course, cease with macroscopic objects, so far as Rothamsted is concerned. Illustrations were shown of records of the life-cycles of two soil organisms, crystals of plant viruses and of the lesions caused by such viruses, all of which involve photomicrography. The electron microscope now available at Rothamsted allows these records to be extended right down to the actual particles of virus and particles of clay (Fig. 1) at magnifications of 20–30 thousand diameters.

Fig. 1. THE CLAY MINERAL, HALLOYSITE. ELECTRON-MICROGRAPH TAKEN AT ROTHAMSTED BY DR F M. L. SHEFFIELD. × 20,000.

At the other end of the scale comes the use of aerial photographs (Fig. 2) for observing crops, the first of which were taken in 1925 by the R.A.F., at the request of Rothamsted. As is well known, aerial photographs show up differences completely invisible from the ground, and make possible the recording on a single plate of such differences in crops covering many acres.

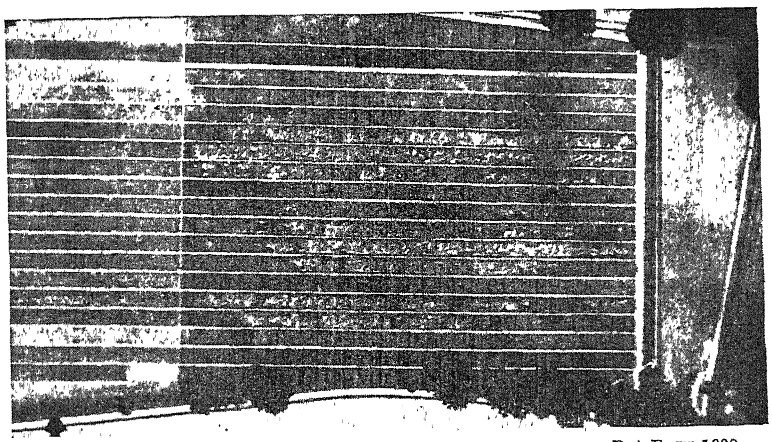

Fig. 2. BROADBALK FIELD, ROTHAMSTED. AERIAL PHOTOGRAPH BY R.A.F. IN 1930. THE DIFFERENTLY MANURED STRIPS, SOME WITH MUCH LODGING, STAND OUT PLAINLY. THE DIFFERENCES BETWEEN FALLOW (RIGHT) AND CROP (LEFT) DURING THE PRECEDING YEAR CAN ALSO BE SEEN.

Most of this 'still' recording work (except electron micrographs and aerial photographs) is done with modern small cameras; the Leitz Leica using 35 mm. film at Rothamsted, or the Zeiss Super Ikonta, giving $2\frac{1}{4}$ in. × $3\frac{1}{4}$ in. pictures at Askham Bryan. The former can be easily adapted for photomicrography by means of the 'Ibso' attachment, or by extension tubes and the sliding copy device, and both are in use at Rothamsted, as well as the Leitz 'Makam' camera, all of which are attached directly to a standard microscope.

Cinematography also finds a valuable place in this work. At Rothamsted, a comprehensive study has been made of the formation of cell inclusions in plants infected with virus, and several stills from this film were shown at the meeting. This film was made using exposures twelve times as long as normal, and when run at the normal rate gives a speeded-up effect which makes possible the detection of many movements which occur too slowly to be seen by direct observation. At Askham Bryan even more use is made of cinematography, partly for educational work and partly for studying the performance of machines. It has been found that the use of the 'aerial' shot is of great advantage in illustrating the movement of farm machinery; a special portable tower 20 ft. high, mounted on a lorry, is used for

making such shots. It is frequently of great advantage to run slow-motion films backwards. In such circumstances many points are obvious which can scarcely be noticed in a normal forward run. Illustrative excerpts of films of a potato digger and a disk-plough in action were shown.

The 'high light' of the afternoon was a speeded-up film of ploughing, made at Askham Bryan, to teach the best methods of laying out and ploughing a field so that idle running of plough and tractor is reduced to a minimum. A suitable field on Teesside overlooked by a cliff was the site, and the whole operation of setting out and ploughing was photographed from the top of the cliff, one picture being taken every second. In this way it was possible to compress two days ploughing into a film which could be shown at the normal rate in 40 minutes. The effect, as well as being very instructive, was amusing, as the tractor and plough appeared to move at about 50 m.p.h.

In addition to these direct methods of employing photography, two uses of the photographic emulsion at Rothamsted were touched upon: spectrographic analysis, both qualitative and quantitative, and X-ray diffraction work on clay minerals, in both of which the sensitive emulsion is used as a recording medium. Standard equipment is used for both—a Hilger medium quartz spectrograph and a Cambridge cylindrical powder camera of 28 mm. radius.

The spectrographic work includes the analysis of soils and plants for such elements as calcium, potassium, sodium, manganese and magnesium, and the detection and estimation of trace elements such as copper and boron and, in one or two recent instances, zinc, lead and chromium in toxic soils. Elements of the first group are estimated from lines excited in the Lundegärdh burner, and calibration curves are plotted with the ratio of line density to background density as ordinate and logarithms of the concentration as abscissæ. Elements of the second group are estimated from lines excited in the carbon and copper arc, using suitable internal standards; for example, tin for boron, the intensity of the tin line at 2496 A. being compared with the boron line at 2498 A.

The X-ray work is indispensable for the identification of minerals found in soil colloids and clays. The electron microscope will undoubtedly help greatly in this work, but as yet, insufficient data are available for the best use to be made of its possibilities. As a general rule, powder diagrams of clay minerals are poor because of the large scattering near the central beam, and aggregate diagrams must be used instead. However, the newer technique of replacing the air in the camera by hydrogen so cuts down the scattering as to make the former more valuable, particularly when obtained from an aggregate.

In the short discussion following the papers, Prof. Yule Bogue raised the question of the limitation of the electron microscope for the examination of biological material by the necessity for working in a vacuum. Dr. Crook, replying, pointed out that the vacuum is only one of the limitations, since the electron-scattering power of the oxygen atoms of the water which constitutes so large a proportion of living material is much greater than the scattering power of the carbon and nitrogen atoms which are the chief 'organic' constituents, and that we can at best hope for an image rather like a radiograph if it becomes possible to use wet material (say, by a freezing technique).

NUCLEAR ENERGY-LEVELS

THE following is a summary of a paper by P. Comparat* which came into the writer's hands by an unorthodox but topical procedure. Printed at Lyons in 1942, it was brought from France by an officer of the Free French forces in 1943. It then found its way into the hands of Prof. D. Saurat, of the French Department of King's College, London, who presented it to the College library. The work described therein was carried out at the Faculty of Sciences, Lyons, initially under the direction of Prof. J. Thibaud. The research occupied a period of four years, full time being devoted to the problem.

Introduction. The first demonstration of the transmutation of nitrogen by rapid neutrons was that of Feather in 1932, using a cloud expansion chamber. The suggested reaction was

$$^{14}N + n \rightarrow {}^{4}He + {}^{11}B + Q,$$

where Q was negative, thus corresponding to an endo-energetic reaction. Subsequent workers, for example, Chadwick and Goldhaber, showed in 1935 with an ionization chamber and a linear amplifier that exo-energetic disintegration also occurred in this reaction. About the same time, Kurie demonstrated that an alternative reaction occurred in which protons were emitted instead of α-particles.

The aim of Comparat's research was to measure the number of disintegrations at various energies of disintegration and to see if the magnitude and distribution of the energy-levels agreed with the current theory. By 1936 the discord between theory and experiment was considerable; the existing theory,

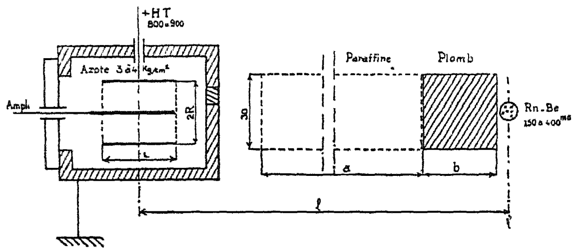

FIG. 1.

based on the two-body concept of the interaction of the incident neutron with the ^{14}N nucleus, predicted a few nuclear levels of considerable width. On the contrary, experiment showed numerous sharp levels. Again, theory predicted identical values for the diffusion and capture cross-sections of slow neutrons, whereas experiment showed a large ratio.

At about this time, Bohr introduced the concept of nuclear transmutation according to which the incident neutron amalgamates with the entire nucleus to form an intermediate nucleus (in this case ^{15}N) of appreciable duration. The intermediate nucleus afterwards disintegrates, for it is in an excited state, with the emission of a heavy particle, often accompanied by γ-radiation. In the special case of nitrogen bombarded by neutrons and boron bombarded by α-particles, the whole process is reversible, thus:

* "Disintegration of Nitrogen by Fast Neutrons; Distribution of the Energy Levels of N^{15}". By P. Comparat. Pp. 96. (Lyon, 1942.)

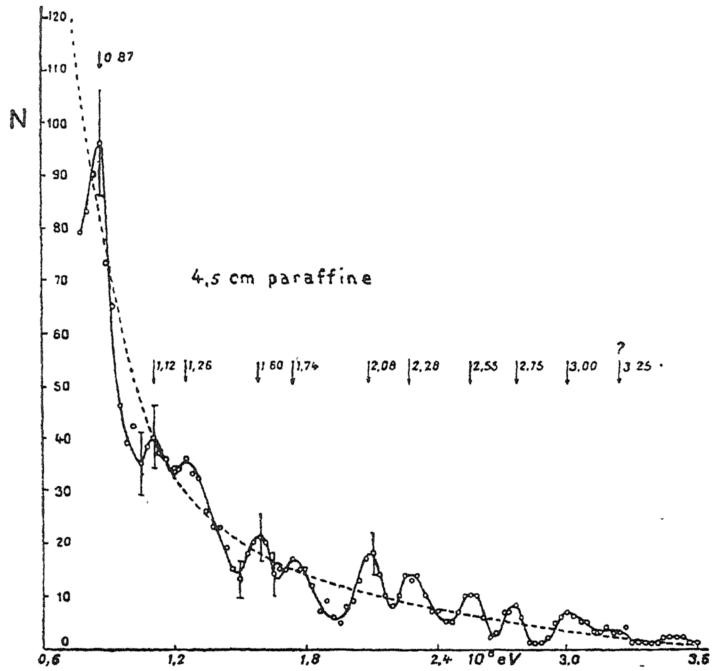

FIG. 2

$$^{14}N + {}^{1}n \rightarrow {}^{15}N \rightarrow {}^{11}B + {}^{4}He \qquad (1)$$

and also

$$^{11}B + {}^{4}He \rightarrow {}^{15}N \rightarrow {}^{14}N + {}^{1}n \qquad (2)$$

Hence the same resonance levels of ^{15}N should be registered in both cases, although the ^{15}N has been prepared by two quite different processes.

By 1937, several determinations had been made of the values of the excited levels of ^{15}N. Wilhelmy had demonstrated the existence of at least five distinct levels for reaction (1), while Maurer had recorded eight levels for reaction (2). Agreement was found between the two workers with four of the energy values. Of the remainder, two further values were assigned to ^{15}N, but the other two were attributed to the excited isotope ^{14}N, formed from the boron isotope ^{10}B, which was present in the experiment. Szalay confirmed Maurer's six levels for ^{15}N and added one more. Finally, Ortner and Protowinsky found a total of twelve groups of particles emitted by ^{15}N in the energy range 1–7 MV.

Experimental arrangement. A diagram of the experimental arrangement is shown in Fig. 1. The principle of the method consists in the use of a proportional counter connected to a linear amplifier and an oscillograph to record the total energy of disintegration of the α-particle together with that of the residual recoiling nucleus ^{11}B.

The counter has a cylindrical anode of about 25 mm. diameter; this was positively charged. The negative electrode was an axial filament 0·5–1 mm. in diameter. The pressure of nitrogen filling the counter was 4–5 atmosphere. At this pressure not only is the ionization increased but also the range of the disintegration products is sufficiently reduced to ensure their being entirely contained in the counter. Zinc was chosen as the metal for the outer electrode on the grounds of ease of purification; the total effective volume of the counter was 15–20 c.c. The potential difference between anode and cathode was about 900 volts and the counter filament was connected to the grid of the first amplifying valve.

The source of neutrons was the usual radon – beryllium mixture of strength 150–400 millicuries. Difficulties arising from the intense γ-radiation were reduced to a minimum by the insertion of absorbing blocks of lead. For details of the linear amplifier, reference is made to an earlier publication of Thibaud, Cartan and Comparat (1938). Special precautions were taken to maintain constant conditions of amplification; for example, changes in resistance were prevented by keeping the apparatus to within 5°–10° C. by thermostat. The sensitivity and reliability of the instrument was checked at frequent intervals with a standard polonium source. As a further check, the constancy of amplification was tested by measurement of the heights of the peaks observed on the oscillograph when a weak A.C. potential was applied to the ionization chamber. The oscillograph was of the Dubois electromagnetic type and this suffered from some zero displacement.

Measurements. The final results were expressed in the form of curves with $N = f\,(E_{a+B})$, where N is the number of peaks corresponding to a total energy of the disintegration products E_{a+B}. Apart from the error arising from statistical fluctuations, which could be readily estimated, the chief source of uncertainty lay in the determination of the exact heights of the peaks. These heights varied from 10 mm. to 50 mm. and it was estimated that measurements

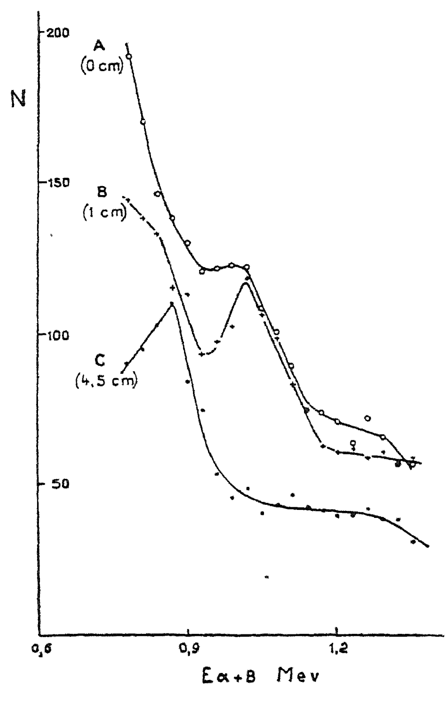

FIG. 3.

could be made to within 0·25–0·5 mm. Hence for smaller energies, corresponding to less than 1 MV., the maximum error was about 5 per cent, while it was correspondingly smaller at larger energies. With an intense γ-ray background, however, the zero band is widened considerably and the error may rise to 3–4 mm. The effect is strikingly demonstrated using α-particles from a polonium source. In the presence of γ-radiation, a typical α-ray peak is reduced in height by more than 50 per cent and increased in breadth by a factor of three or four times. Hence in deciding the reality of the existence of a flattened resonance group, some procedure such as the taking of several independent recordings was carried out to see if the point of inflexion was repeated.

Several sets of measurements were made with the same counter but under somewhat different experimental conditions. Some correspond to a layer of paraffin wax, 0–10 cm. thick, interposed between the source and the ionization chamber; others were made with no wax and only a sufficiently thick layer of lead to absorb most of the γ-radiation. As a control on the effect of the thermal neutrons, a thin layer of cadmium (0–5 mm.) could be inserted, and as a check on the behaviour of the ionization chamber, this could be filled with hydrogen instead of nitrogen. Typical of the measurements made were the following: (a) Ten recordings of 1 hour each made with different thicknesses of wax and with neutrons in the energy range 0·5–1·8 MV. (b) Three recordings of 4 hours each with three different thicknesses of wax —energy range of neutrons 0·75–3·6 MV., and so on.

Results. Some of the results obtained are shown in Figs. 2 and 3. In Fig. 2, the energy range of the incident neutrons was 0·75–3·6 MV. with a thickness of wax of 4·5 cm. The general behaviour, which is quite typical, shows a decrease of intensity with energy, together with distinct groups superposed on the smoothed curve, for example, at energies of 0·87, 1·12, 1·26, 1·60, 1·74, 2·08, 2·28, 2·55, 2·75 (3·00) and (3·25) MV. The figures in brackets are considered to be less well established than the others.

The effect of varying the thickness of the wax while maintaining other conditions constant is shown in Fig. 3 for the energy range 0·75–1·3 MV. Curve *A* was taken with wax absent, while curves *B* and *C* corresponded to thicknesses of wax of 1 cm. and 4·5 cm. respectively. It is noted that some maxima visible with one thickness of wax vanish with another thickness, while other maxima seem little affected. In particular, on passing from *A* to *B*, considerable diminution is observed in the number of low-energy particles, while on passing from *B* to *C* there is a further reduction in the number of low-energy particles; also a pronounced maximum appears at 0·87 MV., that previously at 1·02 MV. having disappeared. Further curves obtained for energies greater than 1·4 MV. give maxima the appearance and position of which are little affected by the presence and thickness of the wax.

Throughout this work, control experiments carried out with hydrogen replacing nitrogen in the ionization chamber gave a smooth curve with complete absence of peaks.

In all, thirty-two distinct groups of energies in the range 0·5–7 MV. were established as follows: 0·60, 0·75, 0·90, 1·05, 1·25, 1·40, 1·60, 1·75, 2·05, 2·25, (2·42), 2·6, 2·78, 3·03, 3·18, 3·33, 3·46, 3·63, 3·76, 4·02, 4·20, 4·36, 4·66, 4·82, 4·98, 5·27, 5·58, (6·04), (6·22), (6·41), (6·66), (7·00).

The average interval is about 0·2 MV. and the spacing is approximately uniform from one end of the energy scale to the other. There is some evidence for a doublet structure between 1·5 MV. and 4 MV. We may note that the rapid decrease in intensity with energy is partly due to the highly inhomogeneous distribution of energy of the neutrons from the source, but it is also partly due to the established decrease in the yield from nitrogen at higher neutron energies. The smoothed curve shows a minimum slope at about 3 MV.; this fact is discussed later.

Interpretation and Discussion. Perhaps the main result of the work is the interpretation of the thirty-two peaks as thirty-two energy-levels of ^{15}N. The question then arises whether all the groups consist of the same type of particles; in particular, do the low-energy groups, so affected in appearance by the introduction of paraffin wax, differ in any way from the groups of higher energy?

Before answering this question, Comparat points out comparisons with other workers. Wilhelmy, Maurer and others, found fewer groups with an interval of about 0·5 MV. Comparat claims that he includes these groups and has demonstrated the existence of the others owing to the superior sensitivity and selectivity of his apparatus, the resolving power of which was estimated at about 0·1 MV. In support of the reality of these levels he quotes recent work by Hansen which also shows a large number of levels although the source was quite different, the neutrons being obtained by the deuteron bombardment of beryllium or lithium.

The particles at lower energy, the production of which is affected by the thickness of paraffin wax, are considered to be protons produced by the reaction

$$^{14}\text{N} + {}^{1}n \rightarrow {}^{15}\text{N} \rightarrow {}^{14}\text{C} + {}^{1}\text{H} \qquad (3)$$

The particles of higher energy are α-particles produced according to reaction (1). The existence of two groups of particles explains the change in shape of the smoothed curve at about 3 MV. The curve is assumed to be compounded of two curves, one giving the yield of protons and the other that of α-particles, the latter curve having a maximum in the region of 3 MV. Careful examination shows that at very low energies the curve again shows a change of shape and this is attributed to a third type of interaction, namely, the elastic recoil of nitrogen nuclei on neutron impact.

Comparat conceives the possibility of an apparatus of higher resolving power demonstrating the existence of still more levels of ^{15}N. That the number of undiscovered levels should prove large he considers improbable on the practical grounds of the reproducibility of existing groups under conditions of varying sensitivity of his apparatus and on theoretical considerations of the spacing of the energy levels of light nuclei. Theory also supports the view that the low-energy particles are protons, since α-particles of such low energy would have very great difficulty in penetrating the potential barrier of the nitrogen nucleus.

By extending these experiments to oxygen and other elements a veritable nuclear spectroscopy of energy levels could be evolved. Valuable information on nuclear structure might then be forthcoming by examining the distribution and width of energy levels as a function of the number of nuclear particles, thus throwing light on the nature of the forces which bind these nuclear particles together.

F. C. CHAMPION.

CENTENARY OF ZOOLOGICAL TEACHING IN TRINITY COLLEGE, DUBLIN*

By PROF. J. BRONTË GATENBY

IN April one hundred years ago, the Board of Trinity College, Dublin, appointed Robert Ball as director of the Museum, with rooms and facilities for delivering lectures "illustrative of its contents and uses". The study of natural history in the University of Dublin began much earlier with the work of William and Thomas Molyneux, grandsons of the Englishman, Sir Thomas Molyneux, Chancellor of the Exchequer in Ireland in 1558. It was William Molyneux who, in 1684, demonstrated the flow of the blood in the newt, by means of the microscope. Whitley Stokes, father of the great Sir William Stokes, the physician, was appointed professor of natural history and curator of the Museum in 1815. His lectures dealt with "Volcanic Theory and Igneous Origin of Rocks, different portions of Zoology, Mineralogy and a Course in Mining and Metallurgy, and with the Natural Resources of Ireland". In 1791, Whitley Stokes was put on trial for his alleged implication in the United Irishmen Movement. He suffered much for his political opinions.

After the appointment of Robert Ball, the study of zoology was not pursued vigorously because his lectures did not have the status of a university subject. Ball, who was a Civil servant in the Chief Secretary's office, was retired on pension by the Government in 1852 on the ground that he "devoted much attention to scientific pursuits, and it was not expedient that public servants should be thus occupied". Ball died in 1857, and in the same year, after his death, the Rev. Samuel Haughton, F.R.S., later professor of geology, announced that the Board of Trinity College had promoted the study of zoology to a recognized university subject. Haughton took an active interest in the development of the School of Physic at Trinity College, and was responsible for bringing in first-class men from outside, such as Alexander Macalister (later professor of anatomy at Cambridge) and Daniel Cunningham (of Edinburgh), whose two sons, Admiral Sir Andrew Cunningham and General Sir Alan Cunningham, have had remarkable careers in recent times. After Robert Ball, the human anatomist Robert Harrison was appointed the first lecturer in zoology, a position he occupied for two years. Afterwards, Edward Percival Wright was appointed lecturer, and then in 1868 became the first professor of zoology. Wright transferred to the Botany School of Trinity College in 1869, and Alexander Macalister was brought in from the College of Surgeons of Ireland as professor of zoology (and comparative anatomy) in 1870. Later, Macalister became professor of human anatomy and chirurgery in Trinity College; he went to Cambridge in 1883. He was succeeded by William Henry Mackintosh as professor of zoology in 1879, who held the chair for forty-two years. He was at the same time registrar of the School of Physic, a position which needed considerable work; his interest in theology and missionary teaching also made inroads in his time, so that he did not publish any original work in the middle and later periods of his life.

It is of interest to zoologists to notice that George James Allman, the authority on Hydrozoa, was appointed professor of botany in Trinity College in 1844, and that the foundations of his exact knowledge of various groups of Cœlenterata were laid in Dublin. Allman was professor of botany in Dublin for twelve years, going to the chair of natural history in Edinburgh in 1856. James Allman was born at Bandon, Co. Cork, in 1812, and at first studied for the Irish Bar. Later he abandoned law and entered the College of Surgeons. He obtained what training he had in science, partly at the Irish College of Surgeons and partly in various private medical schools which then flourished in Great Britain and Ireland. Allman was attracted to the study of the Cœlenterata, after hearing a paper on a "large and beautiful collection of zoophytes" made by a Mr. A. H. Hassell, a Dublin amateur zoologist.

Another great College of Surgeons graduate who did much for the Trinity College School was Alexander Macalister. His father had been brought to Dublin in 1830, as secretary of the Sunday School Society of Ireland. When a small boy, Alexander Macalister was befriended by the curator of the Glasnevin Botanical Gardens, and on his advice, sent to the College of Surgeons at the age of fourteen, becoming a qualified medical man three years later. In view of the fact that Macalister's schooling was poor, it is astonishing that Dr. E. Barclay-Smith (*J. Anat.*, **54**; 1919–20) was able to write of him, "he was an able mathematician and familiar with many languages both living and dead. In Archæology, Zoology, Egyptology, Theology, Biblical History . . . he was an inexhaustible mine of knowledge". Macalister was for thirty-six years professor of anatomy at Cambridge. Macalister was born in 1844, the same year that George James Allman and Robert Ball became members of the staff of Trinity College, Dublin.

* From an address delivered to the Dublin University Biologica Association on May 22.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Saturday, June 10

INSTITUTE OF PHYSICS (ELECTRONICS GROUP) (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Discussion on "Some Aspects of High Vacuum Technique, viz., High Vacuum Gauges and Glass Manipulation" (to be opened by Dr. M. Pirani and Dr. B. P. Dudding).

Monday, June 12

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 5 p.m.—Mr. Gordon Manley: "Topographical Features and the Climate of Britain".

Tuesday, June 13

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 1.30 p.m.—Dr. Elise J. Baumgartel: "Some Observations on the Prehistory of Egypt".

QUEKETT MICROSCOPICAL CLUB (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Mr. C. H. Caffyn: "Rocks and their Structure".

Wednesday, June 14

INSTITUTION OF ELECTRICAL ENGINEERS (MEASUREMENTS SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 3.30 p.m.—Discussion on "The Consumer's Supply Control Unit of the Future and its Effect on the Design of the Electricity Meter".

Thursday, June 15

BRITISH PSYCHOLOGICAL SOCIETY (INDUSTRIAL SECTION) (at the National Institute of Industrial Psychology, Aldwych House, Aldwych, London, W.C.2), at 1 p.m.—Mr. H. G. Maule: "Some Aspects of Factory Inspection in War Time".

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 3 p.m.—Dr. H. L. Hamburger: "The Mathematical and Historical Background of Hilbert's Theory of the Continuous Spectrum".

CHADWICK PUBLIC LECTURE (at the Chelsea Physic Garden, Swan Walk, Chelsea, London, S.W.3), at 4 p.m.—Dr. B. Barnes: "Vegetation and Human Well-Being".*

Saturday, June 17

BIOCHEMICAL SOCIETY (in the Physiology Department, University College, Dundee), at 2 p.m.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

APPRENTICE SUPERVISOR by large Engineering works to supervise educational and training schemes for apprentices and young persons (Nottingham district)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C 2 (quoting Reference No. C.2021XA) (June 14).

PROFESSOR OF BOTANY, ASSISTANT LECTURERS IN ECONOMIC HISTORY, GEOGRAPHY, BOTANY and ZOOLOGY, ORGANIZING TUTOR IN ADULT EDUCATION for Derbyshire, and a TUTOR IN PSYCHOLOGY—The Registrar, University College, Nottingham (June 14).

HENRY MECHAN CHAIR OF PUBLIC HEALTH—The Acting Secretary of University Court, The University, Glasgow (June 15).

SPEECH THERAPIST—The Director of Education, Education Offices, 15 John Street, Sunderland (June 16).

ASSISTANT (with Graduate or satisfactory industrial qualifications) to take MATHEMATICS, ENGINEERING, SCIENCE and DRAWING—The Principal, Hendon Technical College, The Burroughs, Hendon, London, N.W.4 (June 17).

LECTURER IN DIETETICS in connexion with Course leading to University of London Academic Post-Graduate Diploma in Dietetics—The Secretary, King's College of Household and Social Science, c/o University College, Leicester (June 17).

LECTURER IN THE ELECTRICAL ENGINEERING DEPARTMENT—The Registrar, Technical College, Sunderland (June 17).

HEAD OF THE DEPARTMENT OF PHYSICS in the Bradford Technical College—The Director of Education, Town Hall, Bradford (June 17).

METALLURGIST by Firm of Engineers with wide interests (Ph.D., or equivalent, minimum technical qualification)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.2286XA) (June 17).

ASSISTANT MASTER (full-time) in the Smith Junior Nautical School to teach mainly MATHEMATICS and SCIENCE—The Director of Education, City Hall, Cardiff (June 19).

HONOURS GRADUATE IN ENGINEERING to teach ENGINEERING SCIENCE, DRAWING and MATHEMATICS in the Merthyr Tydfil Technical School—The Director of Education, Education Department, Pontmorlais, Merthyr Tydfil, Glam. (June 21).

QUALIFIED ENGINEER by Tyre Manufacturers to direct experimental work on test rigs (location, Wiltshire)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2098XA) (June 21).

DEPUTY CHIEF ENGINEER (location, City of Manchester)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. D.834XA) (June 21).

DEPUTY BOROUGH ELECTRICAL ENGINEER (location, County Borough of St. Helens)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C 2 (quoting Reference No. D.851XA) (June 21).

PHYSICIST for essential War Work (work would include experience in various research departments of a North London firm specializing in optical instruments for scientific and industrial research and control)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. A.518XA) (June 21).

BOROUGH ELECTRICAL ENGINEER—The Town Clerk, Town Hall, Wimbledon, London, S.W.19 (June 23).

DEMONSTRATOR (man or woman) in the CHEMISTRY DEPARTMENT—The Warden and Secretary, London (Royal Free Hospital) School of Medicine for Women, 8 Hunter Street, Brunswick Square, London, W.C.1 (June 23).

PRINCIPAL ENGINEERING ASSISTANT on the permanent staff of the Buildings Department of the Kent County Council—The Council Architect, Kent County Council, Springfield, Maidstone (June 24).

ASSISTANT LECTURER IN MATHEMATICS—The Registrar, The University, Manchester 13 (June 26).

CHEMICAL ENGINEER for Aluminium Powder and Paste Works (location, Middlesex)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2149XA) (July 1).

LECTURER or SENIOR LECTURER IN GEOGRAPHY, and an ASSISTANT LECTURER IN GEOGRAPHY—The Registrar, The University, Manchester 13 (July 10).

JOHN RANKIN CHAIR OF GEOGRAPHY—The Registrar, The University, Liverpool (July 31).

W. H. COLLINS PROFESSORSHIP OF HUMAN AND COMPARATIVE PATHOLOGY—The Secretary, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2 (July 31).

SENIOR LECTURESHIP IN THE DEPARTMENT OF METALLURGY of the University of the Witwatersrand—Dr. W. Cullen, 4 Broad Street Place, London, E.C.2 (July 31).

LECTURER IN CIVIL ENGINEERING—The Registrar, Municipal College, Portsmouth.

LECTURER (full-time) IN MECHANICAL ENGINEERING—The Principal, Handsworth Technical College, Golds Hill Road, Handsworth, Birmingham 21.

GRADUATE IN ELECTRICAL ENGINEERING, and a GRADUATE (or equivalent qualification) IN BUILDING OR STRUCTURAL ENGINEERING, in the Darlington Technical College and Technical School—The Chief Education Officer, Education Offices, Darlington.

LECTURER IN ELECTRICAL ENGINEERING (mainly for teaching Senior Day and Evening students), a LECTURER IN MECHANICAL ENGINEERING, and a LECTURER IN CHEMISTRY (with subsidiary MATHEMATICS, PHYSICS, or BIOLOGY), in the Southend-on-Sea Municipal College—The Chief Education Officer, Education Offices, Warrior Square, Southend-on-Sea.

LECTURER (full-time) IN MECHANICAL ENGINEERING, and a MASTER to teach SCIENCE and MATHEMATICS in the Junior Technical School for Boys—The Principal, Wimbledon Technical College, Gladstone Road, Wimbledon, London, S.W.19.

SCIENTIFIC APPROACH TO HOUSING PROBLEMS

THERE can be no mistaking the extent to which dissatisfaction is rapidly growing at the Government's failure to take and announce its fundamental decisions in regard to the planning and development of the land and the location of industry in Britain. Mr. Dalton, speaking in the House of Commons on June 7, stated that the Government accepts the main ideas of the Barlow Report, but we still await information as to the measures by which effect is to be given to the general policy of planning. The preparation of detailed housing programmes is already a matter of urgency, but is as yet impossible because neither planning authorities nor private developers know what are to be their respective powers. Again, housing policy is intimately related with industrial location policy, for local authorities cannot proceed with housing plans if they are uncertain where the people are to be working.

What perhaps has brought home generally the danger of piecemeal planning is the Minister of Health's admission that the first 300,000 permanent houses are to be built on sites chosen without reference to any sort of national policy for planning the use of land. More than half these sites were bought by authorities whose choice was dictated by local interests and circumscribed by private rights, and Mr. Willink appeared to be quite unconcerned that the remainder should be purchased by authorities still without guidance as to whether public interest is to be the effective determinant in the use of land, let alone whether, from the national point of view, the particular sites those authorities have in mind ought to be used for housing. This is the negation of national planning, and has rightly received forthright condemnation in one of the latest interim reports from the Central Committee on Post-War Reconstruction of the Conservative and Unionist Party Organization.

This report, "Foundation for Housing", prepared by the Conservative Sub-Committee on Housing, with Sir Harold Bellman, J. D. Trustram Eve and K. M. Marr-Johnson as its technical advisers, insists that the first step in framing a housing policy must be to determine where the houses shall be built. This depends first and foremost on the location of industry; but while housing is a non-controversial issue in party politics to-day, many fail to realize, as this report points out, that without planning on national lines a successful housing policy is impracticable. The sub-committee "views with grave apprehension the results which are likely to accrue if housing policy is pressed ahead without preliminary decisions on questions of location of industry and in advance of a solution of the problem of compensation and betterment. . . . Activities of different Government Departments, valuable as they may be, are no substitute for a single comprehensive policy on the issues of location of industry and the protection of agricultural land. We cannot therefore press too strongly for the formulation without delay of national policy on these fundamental points."

In this attitude the Committee should be assured of wide support. It has been repeatedly urged in these columns that failures and faults in our inter-war legislation have been due to the absence of a sufficiently national and positive policy in such matters as the geographical distribution of industry, the protection of agriculture, the co-ordination of transport and the control of the growth of our cities. The warning in this report that, in the absence of an early announcement of the Government's planning policy, the train of housing is in danger of being diverted on to the wrong track, needs the more emphasis in view of the approval with which the pre-fabricated houses have been welcomed, in spite of the warning that they are a temporary expedient.

A particular recommendation of the report is that, as a first step to a forecast of the future distribution of the industrial population, an immediate study should be made by the central authority of the location and extent of war factories throughout Great Britain, of the transport facilities which are available in each case and of the provision, temporary or permanent, for the accommodation of labour. That recommendation is in keeping with the recent report of the Welsh Reconstruction Advisory Council*, which indicates that the Council regards the conduct of a continuous survey of current developments in industry, agriculture and the public services as an important part of its task, and emphasizes the desirability of the regional offices of the Ministry of Production and the Supply Ministries keeping the Council informed of important changes in the location of new plants, in production programmes at particular existing plants and in projects for the post-war use of war factories. A like emphasis on organic evolution, the continual reaction to changing environment based on full technical knowledge, not merely of raw materials and processes, but also of markets, and the participation of scientific and technical workers, not as the tools but as the guides of the politician and financier, characterizes the presidential address of Dr. F. J. North to the South Wales Institute of Engineers.

None the less, the Conservative Sub-Committee insists on its main point, that only by creating effective machinery for the attainment of the three main objectives agreed upon unanimously by the Barlow Commission, and by solving in one way or another the problem of compensation and betterment, can the Government lay the foundation of a successful long-term housing policy. While the Committee welcomes the appointment of a Minister of Reconstruction, it looks for the publication of the promised White Paper, in which it hopes to find proposals for the early creation of a central authority as envisaged in the Scott and Uthwatt Reports, as well as the Barlow Report. In the absence of a single comprehensive policy on the issues of the location of industry and the protection of agricultural land, it sees no alternative to the continued promiscuous growth of the cities of Britain and the drift of the people from the countryside, with ensuing aggravation of all the evils which must inevitably result.

Nothing that has yet been said on behalf of the Government has dispelled a widespread suspicion that official allegiance to national planning is little more than the enforced acknowledgment of a principle which it would be political folly to disregard, but which it has proved inconvenient to translate into practice. Similarly, the belief is hardening that the reason for the delay is due not to the admitted difficulty of reaching an agreed decision on the compensation and betterment proposals of the Uthwatt Committee, but to unwillingness to do so. In its memoranda to local authorities last November, the Ministry of Town and Country Planning gave a lead, but the plan for Plymouth recently published shows how weak are the Ministry's suggestions for avoiding coastal ribbon development in the present uncertainty and absence of legal powers.

This plan for Plymouth is in some respects more far-reaching than the County of London Plan prepared for the London County Council by J. H. Forshaw and Prof. Abercrombie. More than a key to the future of Plymouth itself, it aims at preserving the diverse features of the neighbouring area, one of the most beautiful regions of England, and for this purpose Prof. Abercrombie and Mr. J. Paton Watson's proposals assume the support of the neighbouring rural and county councils. They visualize the metamorphosis of the city from an area clogged and untidy into one decentralized into planned communities, on the basis of a stable population, with the central mass lightened, and a series of suburban satellites.

In spite of the wide appeal of this attempt, not merely to remodel Plymouth but also to improve for the nation the amenities of an entire region, these features of the plan are not the most important at the moment. Here once again is conclusive demonstration that housing by itself is not enough. Still more important is the demonstration that with proper planning and with the aid of the Government by pooling nationally the differing values of land, much of the cost of the scheme can be offset, and any small cash loss would be more than balanced by gains in other ways. Again, here is a convincing demonstration of the national value—if not necessity—of co-operation on a regional basis in planning reconstruction. Only by such co-operation can the district be safeguarded from irreparable damage.

There could, in fact, have been no more timely demonstration to the public and to Parliament of the kind of Government help that is essential. Here is the evidence that local reconstruction cannot be carried out either by private enterprise or public bodies without the security which Parliament must give. Statutory powers are needed now for the immediate acquisition as reconstruction areas of districts which have been 'blitzed' and for their purchase at pegged prices of land. Public ownership is vital, and the local authority must also be able to look to both a central pool for compensation and to a regional policy and a national pool so that betterment and depreciation may be equated.

The first major task of the housing programme

* Welsh Reconstruction Advisory Council. First Interim Report. (London: H.M. Stationery Office, 1944.) 2s. net.

in Britain is clearly that of making good the damage due to enemy action and the slower but equally destructive ravages of war-time neglect. Then will come the work of overtaking the arrears of a hundred years neglect by providing every family with a separate and generously designed dwelling and by establishing an adequate reserve. Both these tasks are, as the Plymouth plan shows, related to planning in wider fields, and this is no less true of housing policy in the next period when it is determined by the need for replacement. This is well brought out in a P E P broadsheet entitled "Old Houses" which, giving an interesting analysis of the social obsolescence of housing, emphasizes that the volume of replacement should depend on the number of new houses that are needed for their own sake. Any decision as to the amount of replacement should be based on a close analysis of the causes of obsolescence in housing.

This broadsheet is thus of special interest in view of the temporary character of the prefabricated houses intended to meet the immediate post-war shortage, and should facilitate the fuller understanding of this complex aspect of the housing problem. While the rate of deterioration of a house depends on the soundness of the original building, the broadsheet emphasizes that social changes can make houses out of date just as surely as any deterioration in the physical structure. Many of the points made in regard to the effect of changes in the living habits of the middle classes, the character of a neighbourhood, the growth of road traffic or industrial location are so obvious as to be almost trite, but their implications are seldom thought out or realized, and the broadsheet proceeds further to show the exact bearing of obsolescence on the post-war housing programme.

Obsolete housing can be dealt with either radically by demolition and replacement, as in slum clearance, or remedially by rehabilitation. The former is the proper course where the original design and layout were poor and mean; but the only sound test as to when the original design and layout should be considered so inadequate as to call for demolition must be selective and designed to destroy and replace none except unfit houses whatever their age. P E P suggests that local authorities should be in a position to adopt a flexible minimum standard and to require all houses to conform to that standard. It is equally important, though more difficult, to reduce the rate of obsolescence of new houses, and in this field the report of the British Building Mission on Building Methods in the United States and the admirable series of Post-War Building Studies which are being issued by the Ministry of Works may well be expected to encourage building the new post-war houses to the highest available standard, while at the same time providing as much scope as possible for flexibility in internal and external arrangements.

Rehabilitation, in its two forms of reconditioning and of conversion, can also play an important part in the post-war housing programme, and the P E P broadsheet points out that little is yet known about the labour economies which would result from large-scale rehabilitation and conversion. The experimental work now being done in Westminster, Islington and other London boroughs should throw some light on the only means by which many houses could be made satisfactory for a new purpose. Moreover, reconditioning and conversion, even if not profitable for individual house-owners, may be worth while from the point of view of the community as a whole, and may, therefore, deserve a subsidy. Again, they have another advantage in checking urban sprawl at a time when the present phase of growth of the town population, as well as of the population at large, is probably approaching its end.

The social function of housing, beyond the mere provision of homes, in promoting also association, neighbourliness, civic sense, architectural dignity, amenity and a feeling of stability finds worthy expression in the Plymouth plan; but it is no easy task to provide a system of housing and type of lay-out which will continuously relate the fabric of a constantly changing society to its even more rapidly changing needs. That is a task in which the constant and thorough application of scientific research to the technical problems of construction is essential, and also the no less assiduous examination of the many social and economic problems involved in the same impartial scientific spirit. The first and most obvious precautionary measure is, as the P E P broadsheet observes, to see that new housing is built to a standard of accommodation and size which is closely related to the needs of the coming generation of householders; that it is built to a scale and in conformity with a lay-out which will permit the establishment and maintenance of a healthy society, provided with public and communal buildings and the requisite social services; that precaution is taken against the hazards of congestion, overgrowth and malformation by an intelligent development plan, understood and appreciated by officials and citizens alike; and that the standards of other community needs—roads, recreation grounds, shops—should be adequate and in proportion.

A secondary objective would be flexibility both in the interior planning of a house, so as to allow some alteration and extension without prohibitive cost, and also as between different dwellings in the same neighbourhood in order to facilitate moves from a smaller to a larger house or vice versa as the family increases or contracts. The maintenance of adequate standards and the decrease of the rate of obsolescence will only in part depend on new housing in the new decades. The major part of the problem will be to deal with existing housing and still more with existing communications and towns, and here the P E P broadsheet leads us back to the fundamental need for control of the use of land in the public interest. The many instances of social obsolescence have arisen out of the chance pattern of land ownerships in old and growing towns, and effective reconstruction can only be carried out on the basis of a temporary or permanent acquisition of large areas of land by a planning authority.

Given the machinery for dealing comprehensively with demolition, development and re-development to a prepared plan and time-table, questions of policy can then be determined with reference to the density

of housing, the case for temporary construction, the life of buildings (for planning purposes) and their functional grouping. But, if the community is to enjoy in its housing programme the full benefits and possibilities which science has placed at its command, it is no less essential that at the centre there should be taken speedily the decisions in regard to the control of land and the problems of betterment and compensation which must be made by the central government. Then local authorities or individuals can prepare and give effect to the plans designed, not only to provide homes, but also to give them a pattern and a setting which preserve as much as possible of our cultural and scenic heritage.

EXAMINATIONS EXAMINED

The Case for Examinations

An Account of their Place in Education with some Proposals for their Reform. By J. L. Brereton. Pp. viii+226. (Cambridge: At the University Press, 1944.) 8*s*. 6*d*. net.

THE author of this book has set before himself three aims: to present a case in favour of examinations, to put forward proposals for their reform, and to give an account of their influence, chiefly in the field of secondary education from about 1858 onwards. As to the third of these aims, his abundant experience in connexion with the Cambridge Local Examinations has enabled him to achieve a noteworthy success. The clear record of historical fact certainly makes the book useful for reference. As to the first two aims, no one knows better than the author that he has been treading on extremely debatable ground.

The book was practically finished when the Norwood Report on Curriculum and Examinations in Secondary Schools was published; but the author was able to add a chapter on that report. The reviewer, having perused Mr. Brereton's book as originally completed, was quite prepared to find him in his final chapter smiting hip and thigh the concocters of the Norwood document, and the expectation was fulfilled. It would be hard to find two pieces of writing on the same theme more utterly at variance than Mr. Brereton's book and the Norwood Report. According to the former, the very life and soul of education are derived from the stimulus afforded by mass examinations, which only need reform in certain directions. According to the latter, no true education is possible in the secondary schools until the prevailing mass examinations, yielding in plenty a stimulus of the wrong kind, have been reformed out of existence.

Manifestly such irreconcilable differences of opinion must be due to causes which are fundamental. Those causes are not far to seek. In their preface, the signatories of the Norwood Report announce their intention to set out suggestions for the freer treatment of the curriculum which is demanded by a "child-centred education" and made possible by the greater freedom secured by their proposed reorganization of examinations. The belief in the child, the individual child, as the centre of all education, gives, they say, a perspective and a vision to education, and assigns to their right places as means to an end all "the paraphernalia of education"—including examinations. That is the idea which pervades the Report from beginning to end. The same idea was taken as axiomatic in the White Paper, which preceded the Education Bill. There we read that "the key-note of the new system will be that the child is the centre of education", not, be it noted, the official or the taxpayer or even the teacher, but the child. Further, to quote the Norwood Report again, "an education which is really child-centred can come about only if freedom is allowed to those who alone can make the individual child the centre of education, namely, the teachers themselves".

From the freer treatment of the curriculum thus based on a child-centred education Mr. Brereton entirely dissents. He is quite clear that "Great Britain will not maintain her position in the modern world unless she repudiates the educational philosophy set out in the Norwood Report". He is clear that the Board of Education, in holding as "a cardinal principle" that the examination should follow the curriculum, not determine it, has only upheld a theory which everyone knows to be ignored in practice—and rightly so. He makes much of the stimulus which the prospect of an examination supplies, but little or nothing of the stimulus inherent in the situation when lively youngsters and a capable teacher are jointly intent on the job in hand. He offers definitions of external and internal examinations which imply the superiority of the former because they involve the element of competition. He defends competition, and evidently has little use for the modern progressive teacher's preference for a co-operative ethic in the classroom.

Seeing that an examination syllabus must go far to settle the content of the curriculum, Mr. Brereton makes good suggestions for reform, and in doing so he quotes John Dewey to good purpose. Nevertheless, the name of Dewey looks rather out of place in a book written in defence of our English examination system. The natural opposite of the child-centred school is the adult-centred school. Until recently, the latter held the field, as it largely does to this day. In the present century, however, the idea of child-centred education has emerged almost simultaneously in England and the United States. As an American writer says, "the doctrine of self-expression is assuming a rôle co-ordinate in importance with that of adaptation". From the first, that is, from about 1900, Dewey has been the inspirer of child-centred education in America and to some extent in England. He has, however, shared a common fate of reformers in being misunderstood. Some of his followers, with their project methods, for example, have overdone the sound principle of free self-expression on the part of the child. In his last book, dated 1938, Dewey seeks to correct the tendency of "many of the newer schools to make little or nothing of organised subject-matter of study and to proceed as if any form of direction and guidance by adults were an invasion of individual freedom". In fact, Dewey's philosophy of experience does recognize, even more directly than Mr. Brereton seems to have noticed, what Mr. Brereton calls "the close inter-connection between the development of the higher faculties of the individual and the world of men and things in which he lives". But there is this difference. Mr. Brereton has lived and worked where the examiner has been in the saddle and has ridden that portion of mankind that goes to school, whereas Dewey only mentions examinations incidentally, and only to lament "the spectacle of professional educators decrying interest while they uphold with great dignity the need of

reliance upon examinations" and kindred "paraphernalia". He issues a warning to well-meaning enthusiasts, but there is not the slightest evidence that he would apply such an antidote as our vast and complicated examination machine. He would be more likely to say, trust your teachers, and if they cannot even trust themselves, reform your system until they feel strong enough to do so. In other words, he would assuredly prefer the spirit of the Norwood Report to that of Mr. Brereton's book.

T. RAYMONT.

BRITISH ELECTRIC POWER STATION PRACTICE

Electric Power Stations

By T. H. Carr. Vol. 1. Second edition revised and enlarged. Pp. xii+507. (London: Chapman and Hall, Ltd., 1944.) 32*s.* net.

MORE than 10 per cent of all the coal mined in Great Britain is used in electric power stations, and the electrical energy produced in these stations is an important factor in determining the standard of living of the population of Great Britain. Books on power stations are scarce, so that the appearance of a new edition of the only up-to-date British publication is a matter of considerable interest and importance.

The volume under review comprises a foreword by Sir Leonard Pearce, two author's prefaces, nine chapters and a subject index. The chapters deal in turn with some fundamentals of station design, civil engineering and buildings, circulating water systems, cooling towers, coal-handling plant, ash-handling plant, boiler plant, pipework and turbine plant. Twenty-nine pages are devoted to fundamentals of design. They provide an ill-assorted series of what purport to be general principles relating to plant rating, choice of thermal cycle, choice of voltage of generation, and station operation. Civil engineering works and buildings are considered in a more comprehensible manner; but the treatment remains scrappy. Some of the facts provided, for example, the tables giving floor areas and volumes of boiler and turbine houses per kW. installed, are potentially useful to those who are interested in power station design. Circulating water systems and cooling towers are described in some detail; but insufficient emphasis is given to the fact that modern developments in cooling tower design and construction are having a profound influence on the economics of electricity supply. Coal and ash-handling plants of all the principal types encountered in Great Britain are briefly commented on in the light of operating experience. The chapter on boiler plant deals with chain grate and retort stokers, pulverized fuel systems and apparatus, natural circulation and forced circulation, steam generators, and instruments used in connexion with steam production. A chapter is devoted solely to steam and water pipes, joints and valves. Turbines and their accessories are considered in the final chapter.

The volume is illustrated by 249 figures which are in the main well-chosen, apart from a few which are too elementary to justify their inclusion in an important treatise. The figures provide more and better information than does the descriptive matter.

The author has done his best to emphasize points of special importance, and has been unsparing in his efforts to safeguard his readers from dangers and difficulties encountered in power station design, construction and operation.

His work is pervaded by a sort of naïve enthusiasm which is quite infectious; but this leads him to make numerous interjections which, although intended to help, actually hinder the reader from getting a proper grasp of the subject in general. The English is frequently so faulty that many sentences are incomprehensible. and the work is further marred by several gross typographical errors. The few calculations which are included are of an elementary and inconsequential nature.

There are only scrappy references to American or other foreign plants, and even those which are included are not direct. Power station development in the United States has always been in advance of that in the rest of the world, and many European stations have novel and interesting features which should be made known to our home engineers.

The author has made an effort to supply a long-felt want in British engineering literature. It is evident from the fact that the second edition of his book has been called for within three years that he has had some measure of success. In the opinion of the reviewer, however, the volume under consideration is in most respects of indifferent quality, and does not adequately meet the requirements of specialists interested in power station design, construction or operation.

C. W. MARSHALL.

LANGUAGES, NATURAL AND ARTIFICIAL

The Loom of Language

A Guide to Foreign Languages for the Home Student. By Frederick Bodmer. Edited and arranged by Lancelot Hogben. (Primers for the Age of Plenty, No. 3.) Pp. 670. (London: George Allen and Unwin, Ltd., 1943.) 15*s.* net.

TO anyone who learnt languages in the traditional fashion, Dr. Bodmer's work must bring a feeling of frustration. In the time spent at the average school on memorizing one language, the intelligent student could, by the method here displayed, learn to understand a group of related languages.

The first part of the book deals with the evolution of languages, with alphabet, accidence, syntax and classification. The second part instructs the reader first how to begin the task of learning the essentials of a language, and then gives the basis of Teutonic grammar and of the languages of Latin descent. Part 3 deals shortly with those languages, such as Russian and Chinese, furthest removed from our own, with the history of the artificial languages, and with a suggestion for yet another planned language for international use. Finally, there is a series of basic vocabularies for the Teutonic and Romance languages and of Greek roots of international currency.

Anyone with some knowledge of European languages reading this book will emerge at the other end with an enriched vocabulary, a sounder understanding of their meaning, and a new capacity for interpreting the unknown words in his future foreign reading. In school an enthusiastic teacher could have no better text-book.

For an adult who wishes to learn a language, the reviewer offers the following prescription. Prepare

the way and mount enthusiasm by way of "The Gift of Tongues" by Margaret Schlauch. Proceed next to Part 2 of "The Loom of Language", and finish with the appropriate volume from "The Basis and Essentials Series" edited by Charles Duff. It is only fair to say that these suggested volumes are included in Dr. Bodmer's bibliography.

The reviewer, after the toil of learning French and the consequent enjoyment of its literature, was dashed to discover that the author rates it as having an "ostentation-value as a female embellishment". Although it is no stigma to be unable to speak French, one doubts whether it is wise to applaud Lloyd George and Wilson because Clemenceau had to speak to them in English. Perhaps the outcome of the conversation might have been different if the Anglo-Americans had had some knowledge of French, and with it an inkling of the workings of the French mind.

The planned language here outlined appears in theory to have many points in its favour. In its final form as seen in "Interglossa" by Prof. L. Hogben, one fears that it will probably meet the same fate as its predecessors. If an international language is to be planned, might it not be better to start from a basic accepted language with an added international vocabulary of scientific and technical terms?

An edified and entertained reviewer recommends this book to all students of languages. If any such students happen to have bourgeois tendencies, they will no doubt be occasionally galled by the author's political interpolations to about the same extent as the author would be if he read "Who are the People" by Colm Brogan. J. MARSHALL.

ELEMENTARY PHYSICAL CHEMISTRY

Elementary Physical Chemistry

By Prof. M. Randall and Prof. L. Esther Young. Pp. xiv+455. (Berkeley, Calif.: Randall and Sons, 1942.) 4.50 dollars.

Introduction to Physical Chemistry

By Prof. Alexander Findlay. Second edition, revised and enlarged. Pp. vii+582. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1942.) 15*s*. net.

RANDALL AND YOUNG'S book is described on the cover as for second- and third-year college students and as a broad survey of elementary physical chemistry. It is not easy to equate this with a corresponding treatment in Great Britain. Some of the topics are elaborated in great detail and others, in the reviewer's opinion, are considerably advanced. The early introduction of the idea of flow-sheets for simple reactions is a novelty, and the precise definitions of concentrations and the implications which flow from them is a good but unusual feature in elementary books of this kind.

The volume is produced, possibly owing to war exigencies, in what looks like imitation typescript and is termed 'photolith'. This method gives good illustrations, which are often drawn from industrial practice; but it is rather trying to the eyes and not conducive to prolonged reading. This may be due to habit.

Findlay's volume is written from the British point of view, and its treatment is in marked contrast to that of "Randall and Young". It deals much more with the experimental side of the subject, and does not go so deeply or so dogmatically into theory. It covers most of the usual field in this subject and should prove a useful aid to students who are beginners as well as to those who are a little more advanced. One characteristic feature is the assignment of dates to the workers who are mentioned.

The book starts on the basis of the atomic theory and ends with an elementary discussion of heterogeneous equilibrium. The thermodynamical treatment is a little old-fashioned; activity is only dealt with in elementary fashion. These may be matters of personal taste. The ambiguities in methods of expressing concentration which become important in all but very dilute solutions are not very clearly brought out. This may be an obsession of the reviewer and could scarcely be expected in a book of this standard; nevertheless clarity in such definitions is very helpful in more advanced work.

CHEMICAL ANALYSIS

Textbook of Quantitative Inorganic Analysis

By Prof. I. M. Kolthoff and Prof. E. B. Sandell. Revised edition. Pp. xvii+794. (New York: The Macmillan Company, 1943.) 21*s*. net.

Systematic Qualitative Organic Analysis

By H. Middleton. Second edition. Pp. viii+280. (London: Edward Arnold and Co., 1943.) 8*s*. 6*d*. net.

BOTH these text-books have this in common, that they have entered into a second edition and that deservedly, for they are extremely useful works which, although primarily meant for university students, are profitable to chemists who have proceeded beyond this stage. There, however, the resemblance ends for, apart from the fact that one deals with quantitative inorganic and the other with qualitative organic analysis, they differ markedly in the manner of treatment of their respective subjects. The former is a comprehensive text-book dealing very thoroughly with the theory and quite adequately with the practice of inorganic analysis, while the latter is severely practical and is meant almost entirely for laboratory use. Perhaps both books could gain something one from the other; the American work would benefit if a few more practical examples were included, particularly in electro-analysis, in amperometric titrations and in nephelometry; Mr. Middleton's book would undoubtedly gain if, here and there, some theory were introduced.

In this new edition of "Kolthoff and Sandell" (previously reviewed in NATURE, **139**, 821; 1937) a number of the chapters have been revised, while the sections on errors, organic reagents and spectrophotometry have been expanded. There has also been introduced a discussion on polarographic analysis or, as the authors prefer to term it, amperometric titrations. A folder has been added inside the back cover and carries a leaflet containing atomic weight tables, four-figure logarithms and some gravimetric factors.

The text of the book on organic analysis (the first edition was reviewed in NATURE, **144**, 366; 1939) has not undergone much change. Some of the analytical schemes have been rewritten, while some thirty additional compounds have been included.

Both books are well got up, they are clearly written, and the text is in each case singularly free from errors. G. R. D.

THE LAWS OF NATURE*

By PROF. HERBERT DINGLE
Imperial College of Science and Technology

THE time in which Halley lived was crucial in the history of science in more than one respect, but of all its aspects none is more significant than that which shows the restoration of the possibility of cosmological studies. Astronomy before Copernicus was essentially and altogether cosmological. No heavenly body had an interest of its own; its sole function was to give a clue to the workings of the universe. But with the dawn of the idea that the universe was infinite, and with the almost simultaneous invention of the telescope, the character of the subject changed completely. The bulk of the universe—the infinite company of the stars—was removed from possible comprehension by finite minds, while the previously inscrutable members of the solar system were brought within human ken. Cosmology thereupon became impossible, and the astronomical study of single bodies began. It was Galileo and Newton who resurrected cosmology, though in a new form. The body of the universe might be inaccessible; but its soul—the universal laws of Nature—could be brought within the grasp of the human mind by the new method of "induction of principles from phenomena", which is the crown of Newton's achievement. It is Halley to whom we owe our knowledge of Newton's work, and it is therefore appropriate that in a lecture dedicated to his memory an attempt should be made to estimate the position reached after two hundred and fifty years of effort along the new lines.

Laws of Motion and Laws of Temperature

Broadly speaking, the progress of physical science since Halley lived has culminated in two comprehensive schemes of physical law. The first is typified by Newton's own laws of motion and gravitation, and is represented in our own day by the general theory of relativity and electromagnetic field theory. The second includes the laws of thermodynamics. These two sets of laws have been called 'primary' and 'secondary'. I prefer to call them 'laws of motion' and 'laws of temperature', for the former nomenclature gives a false suggestion of an order of precedence, whereas motion and temperature are, in fact, the two co-equal phenomena of universal significance that together exhaust the scope of physical inquiry. Consider any two pieces of matter at different temperatures anywhere in an otherwise empty universe. Unless our whole conception of things is wrong, one will inevitably move with respect to the other, and it will inevitably change temperature with respect to the other; and in no other respect, so far as we know, will any observable interaction occur. No known physical agency can prevent these effects. Their course may be modified by the introduction of other bodies, but by no known process can the effect of one body on the motion or temperature of another be annihilated.

It is therefore not surprising that the greatest rift in the as yet immature body of physical law should be that between laws of motion on one hand and laws of temperature on the other. Neither group of laws is, of course, as yet completely unified in itself. Gravitational and electromagnetic motions still await a final blending, and the two great laws of thermodynamics also retain a semi-independence of one another. But these divisions are comparatively slight. In the broad view, it is the separation between the domains of motion and temperature that stands out as the great unhealed breach in the unity of physical law.

Now the present laws of motion and laws of temperature exhibit a striking contrast, which in recent years has attracted considerable attention and forms the main theme of this lecture. The most obvious sign of the difference is this. Consider any possible course of events. According to the laws of motion, this might equally well have occurred in the reverse order; but according to the laws of temperature it could not have done so. There is no actual contradiction, of course, for a 'course of events' to which the laws of motion apply is a movement or set of movements, while a 'course of events' to which the laws of temperature apply is a variation of temperatures. We do not, therefore, have to choose between conflicting requirements; but nevertheless the difference is one which would scarcely have been expected in the representation of the behaviour of a single universe, and does not promise well for an eventual fusion of all scientific law into a single scheme.

An example will perhaps make the position clearer. A ball is thrown into the air. As time goes on it gets higher and moves more and more slowly. If this course of events is reversed, we have the ball getting lower and moving more and more quickly, and this is a possible state of affairs. It does, in fact, occur, for after a while the ball comes to rest, and then descends with ever-increasing speed. Next, a hot body is placed near a cold one. As time goes on, the hot body cools and the cold body gets hotter. If this course of events were reversed, we should have the hot body getting hotter and the cold body getting colder, and this is *not* a possible state of affairs. The actual process continues until the bodies come to the same temperature, and then nothing further happens; they remain at the same temperature eternally.

The mathematical expression of the two sets of laws takes account of this difference in the following way. The law of motion of the ball (in the Newtonian form, which is legitimate for this purpose) may be expressed as $F = m\,\frac{d^2s}{dt^2}$, and if we reverse the direction of time by putting $t' = -t$, we find by substitution that the law is still the same, namely, $F = m\,\frac{d^2s}{dt'^2}$. The law governing the changes of temperature of the bodies, however, is $\frac{dS}{dt} > 0$, where S is the entropy of the system; and here if we put $t' = -t$ we obtain the law $\frac{dS}{dt'} < 0$. It is the former law, and not the latter, which expresses what actually happens.

The effect of this difference on our ideas of the history of the universe is profound. It is obvious that changes are taking place, and when we can express the laws of change we can extrapolate to the distant past and the distant future. Now if a law permits only a uni-directional change, difficulties appear which are not necessary when the direction of change can be reversed, for in the latter event a *cycle* of changes may be possible, and the infinitely

* Halley Lecture delivered at Oxford on May 23.

distant past or future may be very much like the present. Some of the energy of the earth in its elliptical orbit alternates between the kinetic and potential forms, and there is no reason, so far as the laws of motion are concerned, why it should not go on doing so from eternity to eternity. But the entropy of the universe is always increasing, and that means that as we go back into the past it gets less and less, and as we go forward into the future it gets more and more. Strangely enough, it is the past and not the future that contains the greater problem, as we can see more easily if we think in terms of simple temperature exchange instead of the more recondite conception of entropy. Since the tendency is for bodies at different temperatures to come to the same temperature, we can easily visualize an ultimate future state in which the whole universe has reached a common temperature; the approach to maximum entropy is asymptotic. But as we go back into the past, we get greater and greater divergences of temperature. The hot bodies get hotter and the cold bodies colder, and this at a more and more accelerated rate until we reach a time when some bodies are infinitely hot and others infinitely cold; and we must suppose that from such a state they have taken an infinite time to come to their present relative temperatures—a conception impossible to reconcile with our experience of the heat capacity and rate of heating or cooling of bodies. It is true that simple variation of temperature does not cover the whole scope of entropy change, but essentially the same difficulty remains however we look at the matter.

The Second Law of Thermodynamics

My purpose here is to analyse the situation thus presented, in order, if possible, to elucidate the difference between the two great schemes of physical law, but before attempting a task of such magnitude, common sense suggests that we should ask whether there is any escape from the Second Law of Thermodynamics, the particular temperature law which is mainly responsible for the dilemma which faces us. Can we find a fallacy in the arguments which lead to it, or alternatively, if it is unassailable itself, can we find reasons why it is not applicable to the whole universe? We must consider this question, but I shall deal only briefly with it, for reasons which will transpire.

In the first place, then, I think that when pressed we must admit that this Law is not irrevocably established. During the brief period in which scientific studies have been pursued, we certainly find that entropy tends to increase; but it does not inevitably follow that entropy has tended to increase throughout all past time and will do so throughout all future time. Lord Kelvin's original statement was: "There is at present in the material world a universal tendency to the dissipation of mechanical energy", and I think we may take the words "at present" as an indication that he was alive to the possibility that the tendency was only temporary. Moreover, since Kelvin's time we have obtained evidence that the danger of extreme extrapolation is not a fanciful one. In our own region of space we find that bodies move towards one another, by 'gravitation' as we call it, but at very great distances they appear to move away from one another. It may equally well be that if we had 'time telescopes' by which to observe the distant ages, we might find a similar reversal in the behaviour of entropy. We certainly have no experience that makes it more legitimate for us to universalize the Second Law of Thermodynamics than it was for the nineteenth century physicists to universalize Newton's law of gravitation.

The point could be put still more strongly, for not only have we no experience of this kind, but we have evidence in the opposite direction. The general theory of relativity, as Tolman[1] has shown, leaves open the possibility that the universe might expand and contract irreversibly without ever reaching a state of maximum entropy. This possibility, beyond the knowledge of the nineteenth century physicists, comes from the reformulation of the laws of temperature made necessary by the requirement of the principle of relativity that the laws of Nature shall be independent of the standard of rest chosen for expressing them.

Again, when we look at the derivation of the Second Law itself, apart from its invariance under changes of co-ordinate systems, we find that in order to make it logically rigorous we have to insert so many provisos that its direct application to the whole universe becomes impossible. Probably the most successful attempt yet made to give precision to the law is that of Carathéodory[2]. An examination of Carathéodory's statement shows, first, that the Law refers only to a system enclosed within a boundary having at least some of the properties of material things; secondly, that since fields of force cannot be altogether obstructed by such a boundary, they must be assumed non-existent before the Law becomes capable of precise formulation; and thirdly, that the boundary must be supposed to have certain characteristics which it is not certain that matter possesses.

This last point requires a little explanation. For the rigorous statement of the Law it is necessary to distinguish unambiguously between 'heat' and 'work' as two forms of energy. This has long been a difficulty, and Carathéodory deals with it in the following way. If, when the system gains or loses energy, the boundary does not move, the whole of the energy gained or lost is to be called 'heat'. On the other hand, if the system *cannot* gain or lose energy without a movement of the boundary, the whole of the energy gained or lost is to be called 'work'. In the ordinary case, however, the energy of the system will change and the boundary will move, and in such a case we are to calculate the work and the change of energy, and the difference must be heat.

This is all very clear, but in order to carry out the programme we must know how to calculate the work and the change of energy. The former presents no difficulty, but the change of energy can be calculated only if we can find a material for the boundary such that the energy inside cannot change unless the boundary moves; in ordinary language, a boundary must be found which is a perfect non-conductor of heat. If we can find such a substance, we can perform known amounts of work on the boundary and measure the energy changes inside, confident that those changes must be equivalent to the work done; and we are then prepared to measure the energy changes when other boundaries are used. This preliminary work requires an indefinite number of experiments to ensure that, in fact, by no possible device can energy cross the boundary unless the boundary moves; but even if we ignore that practical difficulty, another of a theoretical character remains. If we have found our boundary, which is a perfect non-conductor when it is at rest, how do we know that it will remain a non-conductor when it is moving? If it does not, our whole scheme for distinguishing

between heat and work, and consequently the logical basis of our law controlling the transformation of heat into work, collapses, for whenever the boundary moves we are unable to calculate the change of energy inside and therefore unable to distinguish the passage of heat from the performance of work. We can, of course, escape from the logical difficulty by *defining* a non-conducting boundary simply as one which prohibits all change of internal energy while it remains at rest, but in that case we sacrifice the necessary connexion of the theory with the experience which it was constructed to represent. We can imagine a substance which is a non-conductor when at rest but when it begins to move exhibits all the properties of a conductor—for example, a flame placed outside it might melt ice inside—and we should still have to call such a substance a non-conductor and give the name 'work' to the heat which it allows to pass. I do not think it is the intention of Carathéodory's theory to be logically invulnerable at the cost of being no longer an account of the laws of thermodynamics.

The result of all this is, then, that unless the universe has a boundary which necessarily possesses some of the properties of matter and necessarily lacks others which some forms of matter, so far as we know, may very well possess, and unless we can exclude the possibility of fields of force which can penetrate the boundary, we cannot certainly apply the Second Law of Thermodynamics to the universe as a whole. It is interesting to recall that in the early days of the doctrine of the degradation of energy, Rankine[3] sought to evade its application to the universe by postulating the existence of a boundary, whereas now it is the non-existence of a boundary that we invoke to the same end. Rankine's arguments, however, have no weight in the light of present knowledge.

For various reasons, then, we must reject the claim, only too often made, that the universe 'must inevitably' have begun with a bang and be destined to end with a whimper. But this, after all, does not carry us very far. After disposing of exaggerated conclusions, we have still to reach balanced and temperate ones, and none of the considerations just advanced weakens the force of the Law as expressing present tendencies. Over the whole range of space and time that we can cover, we have always found its demands inexorably imposed and met. The fact that we cannot conclusively deduce its universality gives us no ground for denying that it might, nevertheless, be universal, and it is wise to face that possibility and see how, if at all, we can reconcile it with the greater range of possibilities suggested by the laws of motion.

I should say, however, that I cannot accept the view, which has found favour in some quarters, that the operation of the Second Law of Thermodynamics constitutes scientific evidence for a supernatural creation at a particular time in a not infinitely distant past. Such a view would indeed dispose of our problem, but not to my mind in a legitimate way. Our object in science is to give a natural, rational account of things, not to invoke inscrutable, *ad hoc* powers to explain them away. No one would admit the validity of accounting separately for every observation we make as a supernatural result of the divine will. Such an explanation would be rejected, not necessarily because it was felt to be 'untrue' but because it would be irrelevant. Our aim is to relate each occurrence to others, thus forming a rational correlation of experiences, and an event is not released from inclusion in the scheme of correlation because it happened a long time ago. If, then, we postulate a supernatural creation on scientific grounds, it can only be because we have got into a difficulty from which we can see no escape. The proper course in that case is to try again or else admit that we are beaten. It is not fair to insist on a rational explanation of easy things and fall back on supernaturalism for the difficult ones. If we bring in supernatural agencies at one point we may as well bring them in at all points, and save ourselves the trouble of constructing a trivial man-made rational order.

Experience and Terms of Expression of Experience

The problem before us, then, is this. The present laws of motion and laws of temperature show a non-conformity which is scarcely compatible with our expectations or with our hope that we shall one day arrive at a single comprehensive scheme of physical law; and, further, the laws of temperature, when extrapolated towards the past, lead to a state of the universe which we cannot regard as physically possible. To deal with such a problem we must understand clearly the scope and character of physical laws.

Our aim in science, let me repeat, is to give a rationally connected account of our experience. In order to do this, we must choose *terms of expression* which will enable us to relate together experiences which are in themselves distinct and independent. The experiences are unalterable: they are our primary data, and it is the fundamental canon of science that we accept them unquestioningly. Of course, in the physical sciences, we impose certain tests to distinguish those experiences which are fit subject-matter for our purpose from those which we regard as 'illusions' or 'hallucinations' or 'errors of observation', and hand over to the psychologist, but that is merely a process of selection, not of rejection or modification. The terms of expression which we choose for describing and correlating our experiences, however, are at our choice, and we choose those which enable us to give the most comprehensive rationally connected account of experience. Certain terms of expression are so well established that we have difficulty in recognizing that they are at bottom arbitrarily chosen and not the unique inevitable verbal forms which experience must assume, and the first task that faces anyone who wants to obtain a fundamental understanding of science is to distinguish inviolable experience from deposable terms of expression of experience. The latter, of course, form the language in which laws of Nature are expressed, and their term of office, so to speak, sets an ultimate limit to that of the laws.

Let us take a few examples, to make the difference clear. With a certain arrangement of optical apparatus we observe an alternation of dark and bright bands on a screen. That is an experience. We sometimes describe it as an 'interference pattern', and when we do that we imply a system of waves of light which, when they intersect, can reinforce or neutralize one another. In these terms we can get a consistent, and for many purposes altogether satisfactory, way of describing the experience; but it is not a necessary way, although in the last century many physicists would have thought it to be so. We can also think of a swarm of small particles of light, and in those terms we say the swarm is dense in the bright bands while there are few particles or none in the dark

bands. That also gives a consistent, and for certain purposes satisfactory, description of the experience. We can adopt which description we please so far as Nature is concerned, and our choice will ultimately be determined by the power of the respective terms of expression to afford a description of the widest range of experience.

The fundamental arbitrariness of the choice here is now fairly familiar, but there are other phenomena in which it is less so and in which we may not be able to recognize it without some difficulty. Motion affords a good example. What we call motion is an experience, but the expression of motion as a change of position with time is an arbitrary one—extremely useful, of course, and not lightly to be discarded, but still not essential. An occupant of a smoothly running car can determine if he is at rest or moving not by observing any process of change of position with time, but by noting whether the number opposite the stationary pointer of his speedometer is zero or something else, and he can, if he wishes, describe his experiences in terms of his pointer readings without reference at all to the space and time measurements in terms of which an external observer would probably describe them. The speedometer language, in fact, is, in principle, that in which we originally describe most of the motions we observe in the universe, for the spectrum, which informs us whether a star is approaching or receding, is a kind of speedometer in which the displacement of the lines corresponds to that of the pointer. We usually translate this direct expression of the movement into a statement in terms of space and time, but that is merely for convenience; it is not a necessity.

Again, the measure numbers we assign to movements are likewise arbitrary. It is now common knowledge that there is a limiting velocity possible for bodies, namely, a velocity of about 3×10^{10} cm. a second. There is an inviolable experience hidden in this statement, but it is not in that part of it which gives a finite number to the limiting velocity; that is a characteristic of the arbitrary choice of space and time measurements for the expression of motion. If we choose the Doppler effect instead, and measure velocities in terms of the difference of wavelength of spectrum lines, we find that velocities of approach have a finite limit but velocities of recession may have any value up to infinity. Other, equally valid, terms of expression are possible in which *all* velocities may increase up to infinity. What we experience is quite unaltered by the terms of expression we choose, but any 'law of Nature' which requires that bodies at high speeds suffer some intrinsic change of character which makes it inherently difficult for them to move faster is no law of Nature at all, but an illegitimate statement in a language the possibilities of which exceed its lawful scope.

Far-reaching deductions are often made from the supposed fundamental distinction between 'things' and 'processes', the former being static and the latter dynamic. Dialectical materialists make much of this, and from Zeno and Heraclitus onwards, schools of philosophy have been divided into those who attempt to get beneath change to a constant substratum and those who find in change itself the essential characteristic of existence. The fact is, however, that whether a phenomenon is changing or static depends on the terms in which we choose to express it. If we express motion in terms of space and time, we must call it a changing process, and in order to discover whether a body is moving or not, a finite time, however short, must elapse, for we must compare the positions of the body at two distinct instants. On the other hand, if we express motion in terms of the Doppler effect, no change at all is involved. The static position of the spectrum line is the criterion; we do not require two observations at two separate instants, but one single instantaneous observation alone. I have assumed here that the velocity, whether zero or not, is constant, but the same principle holds if it is not. In that case, if we wish to regard the phenomenon as a static one, we must choose an instantaneous criterion of acceleration instead of velocity, and this we find in force. Take the motion of a planet round the sun. We can describe this by stating the successive positions of the planet in time, or the successive velocities of the planet in time, and each of these descriptions shows it as a changing phenomenon. But if we state the gravitational field, and give values of the position and velocity of the planet merely at one instant, we can describe the whole motion in completely static terms, and see the phenomenon as an example of eternal quiescence.

What is true of motion is true also of other things. A lamp burns steadily. In terms of its candle-power it is an example of steadfast constancy; in terms of radiation of energy to space it is engaged in the most rapid and most irrevocable waste known to Nature. Both modes of description are, of course, perfectly legitimate, and it is exactly the same experience that they describe so differently. Similarly, a body at constant temperature may be regarded either as an inert mass or as engaged in a constant interchange of energy with the whole universe. We may, and on occasion do, use both descriptions.

Problems Arising from Terms of Expression

Examples could be multiplied indefinitely, but probably enough has been said to make it clear that the distinction between experience and terms of expression of experience is an important and often a very subtle one, and that problems which seem to be fundamental may actually belong only to the arbitrary terms of expression employed. Such problems are not solved when the terms of expression are changed; they simply become meaningless and disappear, for they have no basis in experience. An example will illustrate how this occurs.

One of the earliest problems presented to the philosophic mind was that of accounting for the movements of the heavenly bodies. The motions themselves were facts of experience. For their description, however, certain terms were necessary; and the early astronomers made the assumption that the stars and planets were carried round the earth on spheres. The spheres had each a simple circular movement, but they could communicate their movements to one another, and the path of the heavenly body showed the resultant movement, from which the separate spherical revolutions had to be extracted by analysis. When we consider that the stars at least, numbering some thousands, all appeared to revolve in precisely the same period round an obviously stationary earth, we can easily believe that the existence of the spheres must have seemed a necessity; but in the light of present knowledge we can see that it was not so, but was a postulate chosen for the purpose of bringing order into the observed motions.

It did so very successfully. Most of the observed motions could be described to a high degree of approximation in terms of simple circular motions, but

certain unanswered questions remained. What were the spheres made of? How were their motions maintained and communicated to one another? Was the concave sphere of one planet coincident with the convex sphere of the next, or was there a space between them? And so on. These were fundamental cosmological questions, and no way of answering them suggested itself.

In the course of time a revolution occurred. The spheres were abandoned, the sun and stars reduced to rest, and the earth and planets conceived as revolving round the sun in elliptical orbits under the influence of a force of gravitation falling off as the square of the distance from the sun in all directions. The fundamental experiences—the observed movements of the heavenly bodies—were now describable equally well, and even better, but in totally different terms. Instead of revolving spheres, there was gravitational force—a postulate quite foreign to the earlier scheme. At the same time, the old unsolved problems simply disappeared. It was meaningless to ask the size or composition of the spheres, or the cause of their motions, because they were not actual existences but discarded terms of expression. On the other hand, however, new problems arose of which the ancient astronomy knew nothing. What were the physical properties of a medium which could take the enormous strain of holding the planets in their orbits and yet offer no resistance to their motions? What was the velocity of the solar system through this medium? Such questions as these now stood in the forefront of universal problems and appeared as the fundamental enigmas of cosmology; but, despite the concentrated attention of the greatest minds, they received no answer.

Gravitational force has now gone the way of the spheres, and new terms of expression have arisen. We no longer think of a planet as chained to a distant sun. It moves quite freely along its path, taking the easiest course in a 'space-time' having a 'curvature' which distinguishes one direction of motion from another. Again the same fundamental experiences are described with a still further improvement, and again the old unsolved problems vanish. There is no force to cause a strain between the earth and the sun, and it is meaningless to ask for the physical properties of a medium created to sustain one, or for the velocity of the solar system through such a medium. These questions belonged to the discarded terms of expression of celestial motions, not to the phenomena of the motions themselves. And, with the new outlook, just as with the older ones, difficulties are associated. One of them, for example, is the non-conformity of the petrified space-like universe which it contemplates with the dynamic universe shown by the laws of temperature.

Source of Incompatibility of Motion and Temperature Laws

As I have put the matter, the suggestion is irresistible that we should look not for the solution of this problem through an examination of the details of current theories, but for its disappearance by a change in the terms of expression of the phenomena. That is indeed what I am going to propose, but before doing so I would like to say that I fully realize that such a course should be undertaken only in the last extremity. When a system of concepts has proved to be applicable over so wide a range as that covered by current physical concepts, it needs a critical and otherwise insuperable impasse to justify even the thought of its displacement. Most scientific problems are relatively so superficial that anything so drastic as a change in the basic terms of expression would be beyond reason. When Uranus was found to move in a puzzling way, Adams and Leverrier did not begin to reform the foundations of mechanics. Rather than do that, they were prepared to call a new world into existence to redress the balance of the old, and they did so within the framework of current mechanical theory. This, of course, was the proper procedure, and, as everyone knows, it was completely successful. Indeed, so accustomed are scientific men to dealing with obstacles which can be removed in this way that they show great and usually justifiable reluctance even to entertain the idea of changing their terms of expression. Nevertheless, there are circumstances in which it is necessary to do so, particularly when one is dealing with fundamental questions involving extended extrapolation. That, I think, is the situation here. Of all physical questions, there could be none more fundamental and comprehensive than the one which we are now discussing; and the same sense of proportion which should make us regard old and tried terms of expression as binding in ordinary matters should induce us to question them when the problem goes to the root of things.

Let us, then, try to strip from our statement of the laws of motion and temperature those parts which belong to the mode of expression, and see if the discordance remains in the character of the phenomena themselves. There is a limit beyond which it is impracticable—at any rate, to begin with—to carry this purifying process, because if we pursued it to the bitter end we should find ourselves left with nothing but bare sense-data inexpressible except by isolated *ad hoc* words between which there would be no possibility of forming even a connected sentence. Prof. E. A. Milne has rightly insisted that, in the last resort, our scale of time measurement—the convention which decides whether a period of time is equal or unequal to another—is arbitrary, and that we might have chosen a very different one. I would go further and say that, difficult as it may be to acknowledge, even the *order* of our experiences in time is, in the last resort, imposed rationally, and is not an inviolable element of the experiences themselves. But we need not, unless ultimately compelled to do so, go to the last extremity. It may be that the source of our present difficulty lies at a higher level of rational thought than that which comes next to bare experience; and if so, it would be as foolish to go at once to rock bottom as it would be to strip ourselves naked to repair a defect in one of the outer layers of clothing. We will therefore accept our sense data, in the order in which we are accustomed to place them, but freed from all entanglement in formally expressed laws of Nature. For convenience I shall speak of this very primitively rationalized experience as 'bare experience'. We will see if in such bare experience we still find a divergence between the phenomena of motion and those of temperature.

We see at once that we do not; the phenomena of motion, equally with those of temperature, show a one-way tendency. Corresponding to the fact that bodies tend to come to a common temperature and not to differ in temperature as much as possible, we have the fact that bodies tend to move together and not to separate from one another. This is the familiar phenomenon of gravitation. In speaking of it as a fact of experience I ignore, of course, the apparent

recession of the extra-galactic nebulæ, partly because, as a bare fact of experience, that is not a motion at all but a characteristic of spectrum lines, only interpreted as a motion when we have accepted certain rather detailed terms of expression of experience; and even then, as the present disagreement among astronomers shows, not inevitably so interpreted. But I ignore it also because, even if it is taken into account, it does not alter the fact that motions show a one-way tendency, but simply indicates that the tendency is in one direction in some circumstances and in the opposite one in others; it does not make the phenomenon of motion indifferent to the direction of time as the present *laws* of motion do. The indications of bare experience can be represented by the simple idealized situation I pictured earlier. Place two bodies at different points in an otherwise empty universe. They will move in one direction, and not the opposite one, with respect to one another; and they will tend towards the same and not more widely divergent temperatures.

This common one-wayness is, in fact, shown in almost all our theories of cosmic evolution, characterizing the motions as well as the temperature phenomena of the universe. Laplace's nebular hypothesis, for example, depicted a primitive diffuse nebula evolving gradually into a complex organization of many bodies, and, quite apart from the laws of temperature, it provided no possibility of the course of events occurring in the reverse direction. Generalizing such ideas, Herbert Spencer's famous definition of evolution, concerned with matter and motion alone, included only a one-way process from the homogeneous to the heterogeneous. Even in detailed phenomena, such as the direction of revolution of the planets round the sun, we recognize that, whatever the laws of motion may allow, the planets do, in fact, go in a particular direction, and we do not regard it as possible that they will change to the opposite one. The actual, as contrasted with the possible, course of events is uni-directional. Somewhere, in building up our structure of laws of motion from the observed facts, we have introduced a liberty of movement which is not in fact taken advantage of, whereas in building up our structure of laws of temperature from the observed facts we have introduced no such liberty. The difference lies in our terms of expression of experience, and not in bare experience itself, and we must look for it there.

SOIL STERILIZATION

IN horticulture, as in other industries, the War has focused attention on ways and means which before 1939 had not received the notice they deserved. Among them is soil sterilization as a factor in food production. How to produce the greatest amount of good food has become an urgent problem for Great Britain, and there is little reason for believing that this need will be much less pressing for some years to come. To produce the quantity and quality of food we require, five things are necessary. Site, soil and cultivation must be suitable, the choice of variety must be correct and pests and diseases must be controlled. All these are important, but not every one has received proper consideration. Pests and diseases, for example, not only cause serious losses in food production, but they also waste time, labour and materials. Thus, by employing measures for the control of pests and diseases, a higher yield per plant can be obtained with greater economy than by merely increasing the number of plants.

The more intensive the system of cropping, the more likely is it that disorders will occur and the more necessary it becomes to prevent their arising. It is not surprising, therefore, to find that the demands of war have focused attention on problems of soil hygiene in the most intensive system of all, the production of crops under glass. Growers have found that yields fall off and soil pests and diseases assume serious proportions unless the soil is partially sterilized by the periodic use of heat or chemicals.

The sterilization of soils used under glass is necessary for either of two reasons. In the case of pot plants, for which virgin soil is almost always used, sterilization kills the pests and diseases normally existing in the soil. In the case of glasshouse borders which have carried the same main crop year after year and become 'soil-sick', partly through the accumulation of various pathogenic organisms and partly due to biological and chemical unbalance, sterilization is necessary to restore the resulting loss in fertility.

Cleaning up the soil by sterilization is fast becoming an indispensable routine practice under glass, and to meet the situation war agricultural executive committees have recently added to their machinery pools, apparatus for the steam sterilization of glasshouse soils. In cases where steam sterilization is not practicable chemical sterilizing agents, such as formaldehyde, are being increasingly used. Thus, the time is ripe for consideration of the methods and problems of soil sterilization, and with this in view a joint meeting for the discussion of the subject was held on April 19, between the Society of Chemical Industry (Microbiological Panel of the Food Group and the Agricultural Group) and the Association of Applied Biologists.

Dr. W. F. Bewley discussed the general aspects of the subject. Soil sickness and the depredations of eelworms were problems which, in the early years of this century, faced the glasshouse growers in the Lea Valley and elsewhere. They found by empirical methods that if the temperature of sick or infested soil was raised to 100° C. for a sufficient length of time, the harmful organisms were killed and fertility restored. The commonest method employed for glasshouse borders was to force steam into the soil to a depth of 12 in. or more by means of perforated pipes or an inverted tray. At first, pressures of 30–40 lb. per square inch were used, and steaming was carried on for 1–2 hr.; to-day pressures of 80 lb. or more are employed and steaming is for 20–30 min. only. For small quantities of soil, baking was commonly practised in earlier years. With this method, however, patchy heating and 'over-sterilization' are dangers, although if the soil is moderately wetted before it is baked the danger is reduced. Before use, baked soil must be left 4–6 weeks "to recover".

Low-pressure steaming is a method rapidly coming into favour. The soil is put into a perforated container which fits on to a trough of boiling water, the steam from which penetrates upwards through the soil. Electric sterilizers, in which the soil is heated either by the passage of the current through

the soil itself, or by heaters, have also been developed. Plant growth is luxuriant following soil sterilization, and it is now clear that the fertility of glasshouse borders can be maintained over long periods if the soil is sterilized every third or fourth year and manure added from time to time to ensure good organic content and texture. As Dr. Bewley pointed out, however, although sterilization of a poor soil makes it temporarily more fertile, sterilization alone cannot change a poor soil into a rich one.

At the same time that soil sterilization methods were being developed by practical growers, critical investigations were started at the Woburn and Rothamsted Experimental Stations (1908–12). It was found that (1) weeds, weed seeds, and most soil organisms were killed at 60° C.; (2) the nitrifying bacteria and Protozoa were also killed at 60°, but the ammonifying bacteria survived 100° and in the absence of their enemies, the Protozoa, rapidly repopulated the soil; (3) heating increased the amount of soluble organic and nitrogenous matter in the soil and there was a temporary excess of ammonia; (4) seedling growth was not infrequently retarded, presumably owing to the increase in the amount of soluble organic compounds, with a consequent excess production of such substances as ammonia; (5) retardation was greatest when rich soils were heated, but no direct correlation could be established between soil fertility and the degree of retardation. It was concluded that "retardation need not cause any anxiety".

From 1920 onwards, high-pressure steam won increasing favour for the sterilization of glasshouse borders in which tomatoes and cucumbers were grown. Curiously enough it did not become popular among growers who raised pot plants from seed, and so late as 1935 very few 'mixed nurseries' regularly steamed their soil. The reason for this reluctance became apparent when, in an attempt to combat soil-borne disease, sterilized soil was first used on a large scale at the John Innes Horticultural Institution. The results were disastrous in the case of one or two species and harmful in varying degrees to a number of others. At the worst, seeds did not even germinate, while commonly seedling growth was much retarded. Mr. W. J. C. Lawrence described the investigations which led to the unravelling of the complex of factors resulting in this sterilization 'check'. Clay and sand did not react to heating; but humus gave a marked reaction. If lime was added to humus, or to a soil containing humus, before it was heated, the reaction was greater still. Prolonged heating also led to retardation. Most important of all, it was found that the addition of water-soluble phosphate (for example, superphosphate) to soil after heating counteracted the 'check' to seedling growth. From these results, and from the appearance of the plants, it was clear that the application of heat to humus resulted in its decomposition and the production of available nitrogenous compounds which, in excess, were too rich a diet for many seedlings. For example, *Primula malacoides* proved to be highly sensitive to soil sterilization by heating, whereas tomato and cucumber were among the most tolerant. In a few vigorously growing species the excess nitrogenous compounds actually accelerated growth even while the plant was still quite young.

It is now clear why steam sterilization, so widely used for the treatment of glasshouse borders, had not become popular in mixed nurseries for the raising of seedlings. The particular plants used in the experiments at Rothamsted were relatively insensitive to the effects of heating, as are the tomatoes, cucumbers and lettuces grown in glasshouse borders; and retardation or other effects were rarely so marked as to be obvious in the absence of controls. Thus, there was no *prima facie* evidence that extra precautions would have to be taken for the seedlings of other species. The variable results from sterilizing different soils could also be explained, the precise outcome depending in the main on the relative proportions of humus, lime and soluble phosphate present. Soils with relatively high humus and lime and low soluble phosphate contents give the greatest retardation when sterilized. Soils with relatively low humus and lime and high soluble phosphate contents give the least retardation. In the light of these findings an improved technique of steam sterilization for seed and potting composts was worked out at the John Innes Institution, and the benefits of soil sterilization are now available for the vast majority of plant species, without any of the various evil consequences.

The practical requirements of soil sterilization by heat can now be stated in precise terms. (i) In glasshouse borders, pests and diseases occur at a considerable depth, therefore thoroughness of heating is the vital factor. The production of nitrogenous compounds in excess is not usually of serious consequence since tomatoes and cucumbers are not planted in the borders until some weeks after sterilization, and even then not as seedlings but as established plants. (ii) For seedlings and pot plants, the vital necessity is to keep down the production of nitrogenous compounds. This can be done by the efficient use of sterilizing bins in which a relatively small expenditure of heat is adequate for the thorough sterilization of the soil. The addition of superphosphate to the soil after it has been sterilized then partially immobilizes any nitrogen still in excess.

High-pressure steam sterilization has disadvantages for the small grower, of whom there are many. The locomotive boiler and steam tubing employed involve a large capital expenditure, and the apparatus is cumbersome to use. Obviously, it was worth ascertaining whether chemical substances in solution would be as efficient as steam but more convenient, especially for the small grower. Investigations were made first at Rothamsted and later at Cheshunt Experimental Stations. No chemical sterilizer proved to be as efficient all round as steam. Wetting and penetration of the soil present difficulties, and in general the action of the chemical sterilizers is more selective than steam. Thus formaldehyde, the best of the chemical agents, restores fertility well, is a good fungicide, but it is not very lethal to soil pests. Cresylic acid, on the other hand, is efficient against pests but is not very lethal to soil-borne diseases and does not restore fertility so well as formaldehyde. If the effectiveness of steam in increasing crop weight in the tomato is taken as 100, then the figures for formaldehyde and cresylic acid may be reckoned to be less than 90 and 80 respectively. Further, whereas steaming need be done only once in every three or four years to maintain soil conditions, the chemical sterilizers must be applied every year. Improvements in the efficiency of the chemical sterilizers may be expected, however, and Mr. A. H. Dodd described the characteristics of some of the newer substances of the high-boiling phenol type.

Since the Woburn and Rothamsted experiments, practically no fundamental research has been done in

Great Britain on soil sterilization; progress has resulted from methods and experiments of an empirical nature. A new lead has now been given by Rothamsted. Mr. H. Lees and Dr. J. H. Quastel described an ingenious method whereby studies can be made of the effects of certain chemical substances on the metabolic activity of the soil microflora. The 'perfusion unit' employed gives reproducible results, and by its aid it has been established, for example, that potassium chlorate has a selective effect on the bacteria concerned in nitrification. Oxidation of ammonia to nitrite proceeds normally; but oxidation of nitrite to nitrate is inhibited. Further, it has been possible to show that the non-production of nitrate is not a direct effect of the potassium chlorate, but results from the accumulation of nitrite. Lees and Quastel were also able to show that chlorate toxicity is greatly reduced by the addition of nitrate to the soil. Vanadium has a similar effect to chlorate, but smaller; an effect which is general instead of specific. Lees and Quastel's method seems to offer excellent possibilities for further attacks on the problem of what happens to soil when it is heated.

What then is the position of soil sterilization in horticulture to-day? By trial and error methods it has been discovered how to secure the greatest benefits with the slightest risk. Too little fundamental research has been done. For example, it is not known whether excess ammonia is the only product of heating which retards seedling growth; indeed it is not even known whether ammonia is the chief agent concerned in retardation. The action of soluble phosphate on sterilized soil, the chemical effects of electricity in electric sterilizers, the wetting and penetration properties of chemical sterilizers, are other examples of problems awaiting investigation. On the applied side much remains to be done in the design of steam and electric sterilizing apparatus, and there is no reason why what now appears to be a remote possibility, automatic and ultra-rapid sterilization of soil on the moving belt system, should not be achieved under commercial conditions. The use of heavy gases, such as chloropicrin, is another field which awaits the attention of the tool designer as much as the soil chemist.

The main conclusions are clear. Under present and anticipated economic conditions in Britain, horticulture cannot go back to the days when infested and sick soil was tolerated in food production. Neither can it go forward, so far as soil sterilization is concerned, without the co-ordination of fundamental and applied research.

W. J. C. L.

OBITUARIES

Mr. J. R. Norman

THE British Museum (Natural History) has suffered a great loss by the death at Tring at the premature age of forty-five and after a long illness of Mr. J. R. Norman, deputy keeper in the Department of Zoology.

Norman was born in London in 1898, and educated at St. Paul's School. His career was then interrupted by military service in the War of 1914–18. He was invalided out of the army in 1918 and resumed his education at the Imperial College of Science and Technology under the late Prof. E. W. MacBride. In 1921 he was appointed an assistant keeper in the British Museum and in 1942 was promoted to a deputy keepership. During the period of the present War he was entrusted with the charge of the branch of the British Museum at Tring.

Norman, after the retirement of the late Dr. Tate Regan, had the care of the fishes, and in this branch of zoology became the leading authority in Great Britain. He was the author of an admirable book, "The History of Fishes", and of numerous technical papers on the subject. Of these the majority deal with questions of taxonomy and morphology over a wide range of fishes and include a monograph on the Heterosomata (the flat fishes) which was published by the Trustees of the Museum. He also described collections of fishes resulting from the "Discovery", "Antarctica", "John Murray" and the "Cambridge Suez Canal" expeditions. His last work, which is on the verge of publication, is a biography of the late Dr. Charles Davies Sherborn of "Index Animalium" fame.

The rearrangement of the Fish Gallery at South Kensington and the guide book to it was his own work, and during his appointment to the charge of the Tring Museum he organized the exhibition there with great success; here he showed the width of his zoological knowledge of birds and mammals in addition to his own special subject. Both places will serve as monuments to his skill and understanding.

Norman was a fellow of the Linnean Society and of the Zoological Society, of which at the time of his death he was a vice-president.

As a colleague he was admirable from every point of view, full of enthusiasm and fertile of ideas for the good of the Museum in general. His kindly disposition made him liberal of help to others.

Owing to the complaint contracted during his military service in the War of 1914–18 Norman was never strong, but the frequent occurrence of ill-health at no time rendered him impatient nor diminished his sense of humour. He did his work and did it well and never complained. He leaves a widow and two children to whom all sympathy is due.

C. FORSTER-COOPER.

WE regret to announce the following deaths:

Dr. H. A. Buehler, geologist and director of the State Bureau of Geology and Mines, Missouri, on March 14, aged sixty-seven.

Dr. J. S. Bury, physician to the Manchester Royal Infirmary and a past-president of the Manchester Pathological Society and the Manchester Medical Society, on June 10, aged ninety-two.

Prof. J. Shaw Dunn, professor of pathology in the University of Glasgow, on June 10, aged sixty-one.

Dr. Robert A. Hatcher, emeritus professor of pharmacology and materia medica at Cornell University Medical College, on April 1, aged seventy-six.

Mr. E. Hatschek, the distinguished authority on colloid chemistry, on June 4, aged seventy-five.

Prof. Edward B. Mathews, emeritus professor of mineralogy and petrography at Johns Hopkins University, on February 4, aged seventy-four.

Prof. W. E. Tottingham, associate professor of agricultural chemistry in the University of Wisconsin, president in 1931 of the American Society of Plant Physiologists, on March 2, aged sixty-two.

Sir Cuthbert Wallace, Bart., K.C.M.G., C.B., president during 1935–38 of the Royal College of Surgeons of England, on May 24.

NEWS and VIEWS

King's Birthday Honours

The following names of scientific men and others associated with scientific work appear in the King's Birthday honours list:

Order of Merit: Sir Henry Dale, president of the Royal Society.

K.C.B.: Sir Walter Moberly, chairman of the University Grants Committee.

Knights Bachelor: Mr. E. Rock Carling, consultant adviser in surgery and adviser on casualty services to Ministries of Health and Home Security; Mr. A. W. Clapham, secretary of the Royal Commission on Historical Monuments, and lately president of the Royal Society of Antiquaries; Dr. W. A. Daley, school medical officer, L.C.C.; Mr. W. Ll. Davies, librarian of the National Library of Wales; Prof. Alexander Fleming, professor of bacteriology in the University of London, discoverer of penicillin; Prof. H. W. Florey, professor of pathology in the University of Oxford, for services in the development of penicillin; Dr. P. Hartley, director of biological standards, National Institute for Medical Research; Dr. H. S. Houldsworth, Controller-General, Ministry of Fuel and Power; Dr. M. F. Lindley, Comptroller-General of the Patent Office; Prof. G. I. Taylor, Yarrow research professor of the Royal Society.

C.B.E.: Prof. J. D. Cockcroft, chief superintendent, Air Defence Research and Development Establishment, Ministry of Supply; Major K. Gordon, joint managing director, I.C.I. (Fertilizer and Synthetic Products), Ltd.; Mr. J. B. Grant, director of the All-India Institute of Hygiene and Public Health, Calcutta; Mr. T. C. Keeley, for services to Government scientific research and training; Capt. R. N. Liptrot, assistant director of research and development, Ministry of Aircraft Production; Dr. B. H. C. Matthews, head of the R.A.F. Physiological Laboratory; Colonel L. Newcombe, principal executive officer and librarian, National Central Library; Mr. E. F. Relf, superintendent of the Aerodynamics Department, National Physical Laboratory; Prof. W. P. Yetts, professor of Chinese art and archæology in the University of London.

C.B.: Mr. R. R. Enfield, principal assistant secretary, Ministry of Agriculture and Fisheries; Prof. L. C. Robbins, director of the Economic Section, War Cabinet Secretariat.

C.M.G.: Mr. C. W. M. Cox, adviser on education to the Secretary of State for the Colonies; Mr. J. B. Hutchinson, geneticist, Cotton Research Station, Trinidad, and cotton adviser to the Comptroller for Development and Welfare, West Indies; Mr. R. S. Mackilligan, inspector of mines and petroleum technologist, Trinidad; Mr. R. W. R. Miller, director of agriculture and sisal controller, Tanganyika Territory.

C.I.E.: Sukumar Basu, secretary to the Department of Agriculture, Bengal; Mr. G. R. Henniker-Gotley, conservator of forests, North-West Frontier Province, India.

Horace Darwin Fund of the Royal Society

The Royal Society has been offered £2,000 by an anonymous donor to establish a fund for the provision of apparatus and materials for restoring the equipment of laboratories and institutions for scientific research in enemy-occupied territory. It has been stipulated that the fund be associated with the memory of the late Sir Horace Darwin, who did so much to promote the development and use of instruments in research and its applications. The Royal Society has accepted the gift, and has agreed to create a "Horace Darwin Fund". It has been a part of German policy to destroy scientific institutions in invaded countries, after looting apparatus or other equipment likely to be of use, and it may be expected that great difficulty will be experienced in re-starting the scientific life of these unfortunate lands. The help which can be given through the provision of instruments and equipment will be an important contribution to the solution of this difficult problem, and will forge another link in the chain of international collaboration. Contributions should be sent to the Treasurer, Royal Society, Burlington House, Piccadilly, London, W.1.

Research Fellowships in the Medical Sciences at Sheffield

The Council of the University of Sheffield has received a notification from Mr. J. G. Graves, of the intention of the J. G. Graves Trustees to endow research fellowships in medical sciences at the University; the Trustees have transferred to the University £25,000 for this purpose. Alderman Graves is already known for his munificent gifts to Sheffield; he had already contributed handsomely to the building funds of the University and in particular he was the donor of the University Union building, completed in 1936, which provided, for the first time under one roof and on an adequate scale, the facilities for that corporate social life of the students which is so essential a part of a university education. By their present gift, the Graves Trustees have placed the University still further in their debt. For many years the University has been an active centre of medical research, and the achievements of Sir Edward and Lady Mellanby and of H. W. Florey are but outstanding examples from a continuous stream of work directed to the understanding and alleviation of man's bodily ills. The gift will allow the appointment, as soon as circumstances permit, of young workers to fellowships where each will, for a substantial period, devote all his attention to the investigation of some important problem in medical science in an atmosphere already most favourable to such endeavour. The gift not only enriches the scientific life of the Medical School and the University; it may well be expected that in time to come it will bear fruit in medical practice of lasting benefit to mankind as a whole.

Society of Instrument Technology

A Society, with the above title, has been formed for those interested in the design, manufacture, use and maintenance of scientific instruments. Its general purpose is the advancement of instrument technology by the dissemination and co-ordination of information relating to the design, application and maintenance of instruments. It will also provide opportunities for discussion, particularly between the designers and manufacturers on one side, and the users on the other. Among other objects of the Society are the technical education of those who wish to enter, or are already in, the industry and dealing with instrument research, design, manufacture or use; encouragement of research into problems relating to instrument technology; standardization of instruments and accessories by collaboration between manufacturers and users; and the status and prestige of those employed in the industry.

Members of Council and officers of the Society are as follow : *President*, Sir George Thomson ; *Members of Council*, Dr. W. J. Clark, Mr. R. E. Iggledon, Mr. G. H. Farrington, Mr. F. C. Knowles, Dr. W. F. Higgins, Mr. D. A. Oliver, Mr. W. B. Wright, Dr. H. S. Gregory, Mr. C. R. Sams, Dr. E. Griffiths, Mr. E. B. Moss and Prof. F. Debenham ; *Hon. Treasurer*, Dr. H. B. Cronshaw ; *Hon. Secretary*, Mr. L. B. Lambert, 55 Tudor Gardens, London, W.3. It is intended to call a general meeting, probably in the early autumn, at which the constitution and rules, as recommended by the Council, will be submitted for the formal approval of intending members.

Supply and Allocation of Raw Materials

THE second annual report of the Combined Raw Materials Board, to January 26, 1944 (London: H.M. Stationery Office, 2*d.* net), states that the policy of the Board during 1943 has been to concentrate on those materials which were vital to the war effort, were actually or potentially scarce during 1942, and continued to demand action on a combined basis for their effective utilization. The principal metals, and the alloying metals, tungsten, cobalt, molybdenum, vanadium, chromium and manganese, have remained under continuous supervision, while supplies of rubber and hard fibres for rope-making remained critical and demanded continual attention and drastic action. Electrical and instrument programmes in connexion with aircraft and military equipment gave rise to great anxiety regarding mica and especially certain critical grades of it ; the same problem of securing an adequate supply and the proper distribution of critical grades brought asbestos within the scope of the Board. The liberation of Madagascar late in 1942 led to a co-ordinated review of supplies of graphite and their allocation, and the loss of practically all supplies of silk at the time when the joint parachute programmes were making heavy calls brought the alternative synthetic fibre 'Nylon' under the Board's supervision. The output of adequate supplies of balsa wood had to be assured to make possible the production of Mosquito aircraft, while balata, bismuth, bristles, mercury, rotenone, pyrethrum and hides all came or were maintained under review during the year.

The nature of the Board's allocations has varied according to the complexity and acuteness of its problems. To ensure the maximum desired or practicable production of a material, and also that each country uses scarce materials economically, the Board works in the closest contact with the operating departments. Problems of shipping and transport have been of prime importance, and certain problems have been treated on an area basis. Combined committees for copper and steel which had been set up in association with the Combined Production and Resources Board at the end of 1942 were supplemented during 1943 by similar committees for aluminium and magnesium, coal, footwear, leather and hides, and pulp and paper. The overall raw materials position did not change radically during 1943 ; but serious new shortages developed in hides and wood pulp, and a Joint Hide Control Office was set up in Washington to co-ordinate the procurement of overseas hides. The overall stringency is likely to continue indefinitely and well into the post-war period, while a combined committee which investigated the forest products situation reported in October that to maintain minimum supplies of pulp products direct action would be necessary to replenish the labour force in the forests and maintain it at the necessary level. Some measure of curtailment of paper consumption is also considered inevitable.

Towards the end of 1943, the Board was faced with new problems of materials coming or likely to come into partly surplus supply, and, in common with the other combined boards, the functions of the Board were also widened to include the responsibility for making allocations necessary to meet the raw material requirements of territories to be liberated from the enemy. There were no major developments during the year in the actual organization of the Board or its machinery. The final section of the report stresses the dependence of both the United States and the United Kingdom on raw materials from overseas, and the relatively ample endowment in raw materials on which they and the other allied industrial powers have been able to draw.

Post-War Plans for Science

A MEMORANDUM on "Post-war Plans for Science", issued by the Association of Scientific Workers, gives a précis of the statement "Scientific Research and the Universities", issued by the Parliamentary and Scientific Committee, and a more critical review of "A National Policy for Industry" issued by 120 industrialists and of the report "Industry and Research" issued by the Federation of British Industries Industrial Research Committee last autumn, all of which have been discussed in NATURE. Commenting on the proposals by the industrialists for the closer organization of industry, the memorandum urges that organization of the community would be necessary to ensure that the spirit of the proposals is given effect and that the compulsory powers are not abused. With regard to the recommendations of the Federation of British Industries, the memorandum directs attention to the absence of any practical suggestion whereby the consumers or the State could participate in the decision whether certain work should be undertaken because the consumer requires it, or that the Department of Scientific Research should be encouraged to spend more on nationally owned and controlled research institutes for various industries where the results would be published for the benefit of all. While the memorandum sounds a warning against sectional interests being allowed to stunt proposals good and proper in themselves, and calls for a wider vision of the national interest, its criticism is marred by the subjective approach. The prejudice against private industry with which the memorandum starts appears to have clouded judgment to the extent that the writer is more concerned to voice suspicions of any proposals from such a source than to submit them to objective and impartial analysis.

Mineral Resources of Tanganyika

THE Department of Lands and Mines (Geological Division), Tanganyika Territory, has issued an account of the mineral resources of the Territory prepared by Sir Edmund Teale and F. Oates (Bull. 16. Dar es Salaam, 1943. 15*s.*). This bulletin contains, in Part 1, an account of the relatively few mineral deposits that are, or have recently been, worked in Tanganyika. Part 2 includes a much longer list of economic minerals the occurrence of which has been recorded in the Territory, though in many cases in small quantities only. Notes on the manner in which these minerals occur are given, with the view of assisting would-be prospectors.

Further and more systematic exploration appears to be necessary before it can be said that the economic possibilities of these deposits can be properly assessed. Part 3 contains a summary of information regarding certain specially selected minerals, for consideration in reviewing the actual and potential mineral resources of Tanganyika, more particularly in regard to war-time requirements.

Staff Selection

A PAPER (*J. Inst. Elec. Eng.*, **91**, Pt. 1, No. 40; April 1944) by Messrs. R. C. Woods and A. S. MacDonald discusses staff selection by scientific methods, and makes reference to the designing of tests and to the means of proving their usefulness. The use of statistical methods is considered, a number of tests being described and samples given. The application of these principles to the staff selection problems in a light electrical engineering factory is described, the procedure for staffing a new department is detailed, and reference is made to the other classes of labour which are dealt with in the factory. A note on the selection of engineer apprentices is included. The last section of the paper deals with the technique of the interview. Finally, the authors mention the origin and growth of their work as indicative of its usefulness, and refer to co-operation between various departments in the factory which are concerned with personnel.

School Hygiene in Peru

ACCORDING to an annotation in the September issue of the *Boletín de la Oficina Sanitaria Panamericana*, school hygiene in Peru includes psychobiological investigation of childhood and adolescence, school health medical supervision and physical education. A special week is also set apart for an intensive programme in health education for the whole country. During the second half of 1941, 10,000 children between six and ten years were immunized against diphtheria. Medical examination of teachers before appointment has become the general practice. Sanatorium schools for tuberculous children, some of which are built in the higher altitudes with appropriate climatic conditions, have been established. Retarded children are being given attention and transferred to special schools.

Earthquakes Registered in Spain

DURING January 1944, twenty-nine earthquakes were registered by the seismographs at the Geophysical Observatory at Toledo. The greatest of these happened on January 16 and registered at Toledo at 00h. 02m. 41s., attaining a ground amplitude of 90μ at the Observatory. The earthquake was destructive in the province of San Juan in Argentina, South America. The nearest earthquake to Toledo during the month occurred on January 7, when eP_gz registered at 12h. 31m. 09s. from an estimated epicentral distance of 230 km.

Gas Industry in Great Britain

THE Minister of Fuel and Power has appointed the following committee of inquiry into the gas industry: Mr. Geoffrey Heyworth (*chairman*), Mr. Stuart Cooper, Sir Jonathan Davidson, Mr. Gavin Martin and Prof. D. M. Newitt. The secretary of the committee will be Mr. A. F. James, of the Ministry of Fuel and Power, to whom all communications should be addressed at the Gas and Electricity Division, Ministry of Fuel and Power, New Oxford House, Bloomsbury Way, W.C.1.

The terms of reference of the committee are: "To review the structure and organization of the gas industry, to advise what changes have now become necessary in order to develop and cheapen gas supplies to all types of consumers, and to make recommendations".

Announcements

FRANKLIN MEDALS for 1944 have been awarded to Dr. W. D. Coolidge, vice-president and director of research for the General Electric Company, for his development of the X-ray tube, and to Dr. P. Kapitza, director of the Institute for Physical Problems, Academy of Sciences of the U.S.S.R., for his work on extraordinarily high magnetic fields, and for designing an efficient liquid hydrogen machine.

DR. S. LIVINGSTON SMITH, superintendent of the Engineering Department at the National Physical Laboratory, Teddington, has been appointed director of research of the British Shipbuilding Research Association recently formed by the Shipbuilding Conference in close co-operation with the Department of Scientific and Industrial Research.

DR. A. J. V. UNDERWOOD has resigned from the position of joint honorary secretary of the Institution of Chemical Engineers which he has held for the last eight years.

DR. R. E. G. ARMATTOE, director of the Lomeshie Research Centre for Anthropology and Human Biology, and honorary physician in charge of Brooke Park (E.M.S.), Londonderry, has been elected a foreign member of the American Association of Physical Anthropologists.

DR. CHARLES OCKRENT, who has been working during the War in the Ministry of Supply and more recently has been acting in an advisory capacity in Scotland on the application of scientific control and instrumentation in industry, has been appointed to the scientific staff of the British Drug Houses, Ltd., as manager of production and development.

THE following appointments have been made in the Colonial Service: R. D. Linton, agricultural officer, Tanganyika, to be senior agricultural officer, Tanganyika; G. W. Nye, deputy director of agriculture, Uganda, to be director of agriculture, Nyasaland; A. S. Richardson, director of agriculture, Nyasaland, to be director of agriculture, Uganda; E. G. Staples, senior agricultural officer, Uganda, to be director of agriculture, British Honduras; A. S. Stenhouse, agricultural officer, Tanganyika, to be senior agricultural officer, Tanganyika; W. A. Burns, G. S. Cowin, M. A. Molloy and N. R. Reid, veterinary officers, Tanganyika, to be senior veterinary officers, Tanganyika.

WE have received from the Freshwater Biological Association a copy of Scientific Publication No. 8 which takes the form of "Keys to the British Species of Aquatic Megaloptera and Neuroptera", written by D. E. Kimmins of the British Museum (Natural History). It provides an admirable account of these insects accompanied by excellent original illustrations of their chief structural features. Its low price of 1*s*. 6*d*. should ensure it being in the hands not only of entomologists but also of all students of the freshwater fauna. It can be obtained from the Director, Freshwater Biological Association, Wray Castle, Ambleside, Westmorland.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Evolution of Modern Man (*Homo sapiens*)

THE discovery of a fossil human skull near Keilor, an outer suburb of Melbourne, is a matter of high importance to students of human evolution, who will certainly welcome Dr. Zeuner's[1] confirmation of the great antiquity attributed to it by Mr. D. J. Mahony, namely, that it represents a native Australian of the last (Riss – Würm) interglacial period. In seeking for the homeland of this ancient representative of *Homo sapiens*, neither Dr. Zeuner nor Dr. Wunderly, who was entrusted with the description of the skull, allude to the most probable source of the aboriginal population of Australia, namely, the early pleistocene races of Java, typified by *Pithecanthropus erectus*.

The first to suspect that the Australian aborigines were related to the ancient Javanese was Hermann Klaatsch, who visited Australia in 1904 to make a study of the aboriginal skull. In a report issued in 1908[2] this passage occurs: "My recent experiences show so many connections between Pithecanthropus and Australian and Tasmanian skulls that I am more inclined than before to accept a very close approximation of Pithecanthropus to the first tribe of human beings". The next link in the chain of evidence came in 1914 when the British Association visited Australia. The Talgai skull was then examined and accepted as probably of pleistocene age, an assumption now vindicated by the discovery of the Keilor specimen, for the Talgai, to my eye, is the more primitive of the two. Then, in 1920, Eugène Dubois published an account of two ancient skulls from Wadjak, in Java; he regarded them (I think rightly) as Proto-Australian in type. Even so late as 1931, I was still in doubt as to the ancestral position of Pithecanthropus[3]. Then, with the discovery of later fossil types in Java by Dr. Oppenoorth in 1932, and the subsequent additions made to the Pithecanthropoid family by Dr. G. von Koenigswald, it seemed to me the chain of evidence that links the Australian aborigine of to-day with Pithecanthropus of the early pleistocene was complete, and I said so in 1936[4]. In a great monograph which has just appeared[5], Dr. Weidenreich has reached independently the same conclusion as to the origin of one type of modern man—the aboriginal type of Australia.

Dr. Weidenreich and I are also in agreement in tracing the Bushman of South Africa from the primitive fossil type found in Northern Rhodesia—*Homo rhodesiensis*; we are also both convinced that Sinanthropus lies on or near the line which gave rise to races of the Mongolian type. Here, then, are three of the present-day types of man traced to separate pleistocene origins. Most of us who, a decade ago, were making a special study of the fossil remains of man believed that we should find, some day, the remains of a type which would serve as an ancestor for all living races, and that we should find this ancestral type spreading abroad in the world, exterminating the other early pleistocene types; all the evidence has gone against this supposition. The only man, so far as I know, who guessed that living human races had, in a physical sense, approached nearer to each other as time went on was the Swiss anthropologist, Karl Vogt[6]. Darwin considered Vogt's suggestion, but rejected it as improbable[7]. Yet it is known that convergence of a very similar nature took place in the evolution of horses.

I have mentioned that as regards the origin of modern races of mankind, Dr. Weidenreich and I have reached a large measure of agreement, all save in the case of that most ancient of Englishmen, Piltdown man (Eoanthropus). Dr. Weidenreich is of the belief that all surviving races of mankind have passed through a "Neanderthaloid" stage in their evolution, a stage which was apparently omitted in the case of Piltdown man. He is therefore removed by Dr. Weidenreich from the list of authentic fossil men, his skull being assigned to a modern type of man, while his lower jaw is given to a fossil anthropoid akin to the orang. Virchow solved the mixed simian characters of Pithecanthropus in a similar way, assigning the skull to an ape and the femur to a man. In England we find it hard to believe that there lived in the Weald of Sussex, in earliest pleistocene times, a modern type of man and a rather human-like ape, and that by some strange chance the bones of these two became mingled in the Piltdown gravel bed. Not only was the Piltdown race alive in England when the rest of Europe seems to have been occupied by human stock of the Neanderthal breed, but also this ancient race appears to have come down to mid-pleistocene times; at least it is on such a supposition we can best explain the characters of the Swanscombe and London fossil skulls.

Another problem bearing on the evolution of modern races has again cropped up in connexion with the discovery of the Keilor fossil skull. This skull exhibits a mixture of Tasmanian and Australian features. Dr. Wunderly explains the mixture by regarding Keilor man as a hybrid—the result of a union between Tasmanian and Australian races. We do not know of the existence of these two races until long after the Keilor period; if we believe in evolution, then our attitude to Keilor man should be to regard him as a representative of the ancestral stock from which both Tasmanian and Australian races have emerged. The same problem arises in connexion with the Skhūl people of Mount Carmel. They possess both Neanderthal and 'modern' (Cro-magnon) features. Dr. McCown and I explained the mixture by regarding the Skhūl people as transitional between the older Neanderthal type and the recent or modern type[8]. Those who maintain that the Skhūl people are the mixed progeny of Neander – Modern parents must first convince us that the modern type of man was in existence before the Riss – Würm interglacial period.

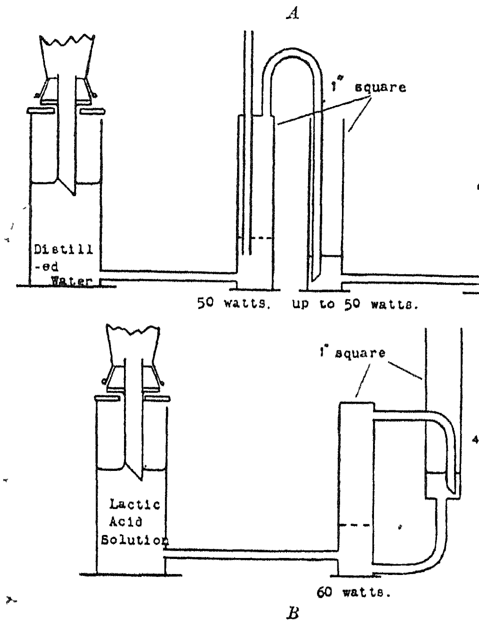
Vaporization of Lactic Acid as an Aerial Bactericide

In an earlier communication[1], an account was given of the bactericidal action of lactic acid vapour. Further work has shown that the methods of vaporization used until that time were inefficient, and that effective bactericidal action is obtained when the concentration of acid vapour in the air is 3·5 mgm./cu. metre.

Lactic acid cannot be boiled at ordinary pressures without decomposition. Dropping the acid or its aqueous solution on to a hot plate also leads to considerable loss of acid. Dispersal as a fine spray is satisfactory from the point of view of avoiding loss or decomposition of acid; but for continuous operation needs cumbersome and expensive apparatus. Lactic acid is, however, readily volatile in superheated steam, and two forms of apparatus for effecting this have been devised and are shown in the accompanying diagram. With appropriate modifications they are, of course, also suitable for the vaporization of other bactericidal substances volatile in steam.



In type A, water is fed from a constant-head feed system into a closed electrically heated boiler. The steam from this boiler is then allowed to bubble through the lactic acid in an electrically heated pot into which the lactic acid is fed from another constant-head feed system. The rate of evolution of lactic acid vapour depends on (*a*) the rate of steam flow, to which it is directly proportional, (*b*) the temperature of the pot, which is maintained at any desired point between 120° and 180° C. by adjusting the heat supply.

In type B an aqueous solution of lactic acid is fed into a closed electrically heated boiler from a single constant-head feed system. The water is largely boiled off and the concentrated lactic acid passes into an electrically heated pot. The steam from the first boiler is allowed to blow off through the lactic acid in this pot. The wattages of the two heaters are adjusted to maintain the second pot between 120° and 180° C. For given wattages the temperature of the second pot and the output of vaporized lactic acid are controlled by the concentration of the initial lactic acid solution, which may be varied from zero up to 20 per cent lactic acid by weight. For smooth working the boiler must have adequate thermal capacity; a mass of 250 gm. of brass is usually sufficient, but twice this is preferable.

Both types, as illustrated, have a maximum output of about 12 gm. of lactic acid vaporized per hour, and have been constructed mainly from brass, with all joints brazed. Corrosion of the metal and formation of non-volatile polymers appear to be negligible under working conditions; but it is probably desirable to flush out the system occasionally. Distilled water must, of course, always be used to avoid furring up the boiler.

Role of Manganese in the Biological Synthesis of Ascorbic Acid

I HAVE adduced evidence[1] that manganese has a specific role in the synthesis of ascorbic acid by plants and animals. Until now the evidence of the synthesis of ascorbic acid in presence of manganese has been chemical; that is, by titration with the indophenol reagent. Evidence that the indophenol-reducing substance synthesized is identical with vitamin C has now been obtained.

Phaseolus radiatus seeds were germinated in distilled water and in separate and mixed dilute solutions of sodium chloride, magnesium sulphate and manganous chloride. The grains germinated in solutions containing manganese, within certain minimal concentration, alone showed a largely increased synthesis of ascorbic acid; the other salts had no effect upon the synthesis of ascorbic acid. Young growing guinea pigs were divided into three groups and kept on a scorbutic diet of oatmeal, 63; bran, 10; casein, 20; linseed oil, 2; codliver oil, 2; sodium chloride, 1; calcium phosphate, 2. One group was supplemented daily with 0·5 mgm. of synthetic ascorbic acid. The second group was supplemented with a given amount of *Phaseolus radiatus* germinated in distilled water for one day and calculated to contain 0·5 mgm. of total (reduced and dehydro-) ascorbic acid. The third group was similarly supplemented with a given (smaller) weight of *Phaseolus radiatus* germinated in 0·002 per cent manganese solution for one day and containing 0·5 mgm. of total ascorbic acid. The experiment lasted three weeks.

The results are given in the accompanying table. The two groups supplemented with germinated *Phaseolus radiatus* showed exact parallelism in their growth-rate, and closely agreed with the growth-rate of the group supplemented with synthetic ascorbic acid. This establishes the identity of the increased indophenol-reducing substance synthesized by *Phaseolus radiatus* when germinated in 0·002 per cent manganese solution with vitamin C.

In another set of experiments guinea pigs (120–150 gm. in weight) kept on the above scorbutic diet were divided into two groups. One group was

Substance fed	Ascorbic acid content (av. of 3 weeks) (mgm./gm original seeds)	Ascorbic acid fed (mgm.)	No. of pigs	Av. initial wt. (gm.)	Av. wt after 3 weeks (gm.)	Av. increase in wt. after 3 weeks (gm.)
Synthetic ascorbic acid	—	0·5	6	115	181	66
Phaseolus radiatus germinated in distilled water	0 80	0 5	6	116	176	60
Phaseolus radiatus germinated in 0 002% Mn	1 03	0·5	6	106	165 5	59·5

given intraperitoneal injections of 25 mgm. glucose dissolved in ½ ml. of distilled water. The second group similarly received 25 mgm. glucose dissolved in ½ ml. of 0·04 per cent manganese solution. The injections were given daily for 14 days and then the animals were killed, cross-sections of the root of lower incisors taken, the histological structure studied and the degree of protection against scurvy judged according to the Key and Elphick[2] scale. The number of animals employed in each group was five.

The animals in the group injected with glucose alone had a degree of protection of 0, showing that no synthesis of ascorbic acid had taken place in these animals. The animals in the group injected with glucose in manganese solution had, on the other hand, an average degree of protection of about 3. Some animals had complete protection (degree 4) against scurvy (see photograph). This proves that the animals injected with glucose in manganese solution had synthesized ascorbic acid, thus affording themselves partial or complete protection.

The experiments recorded above support my hypothesis that manganese is indispensable for the synthesis of ascorbic acid by animals and plants, and that the non-synthesis of the vitamin in primates and the guinea pig is due to an insufficiency of the metal at the seat (jejunum) of ascorbic acid synthesis. Further investigations are in progress.

Dried Potato Products and Nutritional Encephalomalacia in Chicks

THE feeding value of dried potato products has been investigated at the Agricultural Research Institute of Northern Ireland, chiefly from the point of view of their value as substitutes for maize meal and other cereal products in rations for pigs and poultry. Excellent results have been secured with fattening pigs[1,2], in agreement with Woodman's results[3]. Preliminary experience suggests that such products are satisfactory substitutes for maize meal in the rations of laying pullets kept on good grass runs[1].

We have also attempted to replace the maize meal in a practical chick ration by dried potato meal manufactured by drying potato slices in direct contact with flue gases. The control ration consisted of maize meal 51·5 per cent, wheat-feed 20 per cent, fish meal 10 per cent, earthnut cake meal 5 per cent, dried liver meal 5 per cent, cod-liver oil ('controlled mixture') 2 per cent, mineral mixture 1·5 per cent. This ration was based on a successful ration used in assessing the value of dried liver meal produced in Northern Ireland as a riboflavin-rich protein supplement[1].

Replacement of the maize meal of this control ration by the dried potato meal led to serious symptoms of nutritional deficiency and mortality from about the middle of the second week onward. Deficiencies of vitamins A and D were ruled out by the inclusion of adequate cod-liver oil in the rations, the absence of symptoms of rickets and the presence of considerable reserves of vitamin A in the livers *post mortem*; the dried liver meal was known to supply adequate riboflavin[4]; the condition did not respond to dried yeast or to massive doses of thiamin hydrochloride or pyridoxin; and calculation seemed to exonerate pantothenic acid deficiency, especially in view of the absence of dermatitis.

Afterwards, Dr. Blakemore, of the Institute of Animal Pathology, Cambridge, directed our attention to Asplin's work[5] on an outbreak of nutritional encephalomalacia in Great Britain. Asplin's clinical description applies in detail to the clinical picture observed by us, except that we have also noted well-marked intermittent tremors, as though the heat-regulatory system was impaired. Such tremors, however, are included among the symptoms of 'crazy chick disease' (nutritional encephalomalacia) by Titus[6].

We have now repeated these experiments with rations essentially similar to that described above and have confirmed the diagnosis of nutritional encephalomalacia from the occurrence of the characteristic massive œdema of the cerebellum and pinpoint hæmorrhages of its surface in affected chicks;

Prof. J. H. Biggart has very kindly further confirmed the nature of the brain lesions by sectioning.

While our work on this subject is not yet completed, we think it advisable to direct attention to these observations in view of their possible practical significance. It is possible under war-time conditions that potatoes and dried potato products may frequently be regarded as cereal substitutes in chick-rearing rations, which are also likely to contain cod-liver oil. Incorporation of cod-liver oil with cereal products is well known to lead to oxidative destruction of vitamins E, and where the proportion of cereal is low or stale meals are used, nutritional encephalomalacia may be encountered. It is clear that, under war-time conditions, obscure types of leg-weakness other than rickets or curled-toe paralysis (riboflavin deficiency) may be due to nutritional encephalomalacia and should be checked by macroscopic and, where possible, microscopic examination of the cerebellum.

p-Cresol and Œstrone in Urine

THE presence of *p*-cresol in human urine, as well as in the urine of horses, cows and other animals, has been known for a long time. It occurs mainly as a salt of *p*-tolylsulphuric acid. According to Siegfried and Zimmermann[1], the average concentration of *p*-cresol in normal human urine is of the order of 18 mgm. per litre, and in a man with an adrenal tumour a value of 25 mgm. per litre has been reported[2]. In the urine of pregnant mares, Marshall has found that the concentration is 60 mgm. per litre[3].

It is significant that these increases in *p*-cresol are accompanied by corresponding increases in the concentrations of œstrogenic hormones, mainly œstrone, present in the urine, which have been reported as 0·016 mgm., 0·3 mgm. and 10 mgm. per litre respectively in the three cases. The urine of stallions provides an even richer source of œstrone, the concentration reported being of the order of 17 mgm. per litre[4]. We have confirmed this figure for total œstrogen, and in addition have found that the concentration of *p*-cresol in this instance reaches the remarkably high value of 550 mgm. per litre. Approximately 25 gm. of *p*-cresol (benzoate, m.p. 72°; aryloxyacetic acid derivative, m.p. 134°) were isolated from the strong phenolic fraction from 10 gallons of the mixed acid-hydrolysed urine from two stallions. It is also known that the œstrone content of human urine increases progressively during pregnancy, and Falsia[5] has reported that there is a corresponding increase in the *p*-cresol content.

The origin of the phenol and cresols in urine is usually attributed to tyrosine, and in support of this view it has been claimed that the concentration of phenols in urine increases with an increase in protein intake. On the other hand, Fricke[6] has pointed out that the phenolic constituents of urine are most abundant in Herbivora, and has claimed that the quantity in human urine is increased on a vegetable diet. These considerations seem to indicate that tyrosine and intestinal putrefaction may not be the sole source of phenols in urine, and the above correlation between the elimination of œstrone and *p*-cresol suggests the possibility that not only the former but also the latter may be derived from the male hormone or some related steroid. On this basis the *p*-cresol could arise from ring *A* of the steroid molecule, in which the hydroxyl and methyl group are correctly placed. This possible connexion between the natural sex hormone and simple phenols, coupled with the known œstrogenic activity of many phenolic compounds of comparatively simple structure, recalls the suggestion, originally due to Dodds[7], that the true œstrogenic agents may be relatively simple compounds resulting from the breakdown of the cyclopentanopolyhydrophenanthrene system.

A Search for Endemic Areas of Trichinosis in Great Britain

ALTHOUGH the life-history of *Trichinella spiralis* has been known for nearly a century, we are still very ignorant of the epidemiology of trichinosis in man—a gap in our knowledge which remained unsuspected until Hall[1] discovered the frequent occurrence of sub-clinical human infestation in the United States. A repetition of Hall's work more recently carried out in Great Britain by Van Someren[2] and later by Miss M. Young[3] has revealed that a similarly high incidence of infection is to be found here. Interest in the epidemiology of the infection in Great Britain has been still further stimulated by the outbreaks of clinical trichinosis which occurred during the winter of 1940–41 at Wolverhampton, Penrith and Harpenden[4,5] accentuating the urgency for the discovery of the origin of infection.

In the past, it has been generally supposed that outbreaks of trichinosis in Great Britain are traceable to the importation of infected pork, which occasionally finds its way through the meat inspection; but this now appears to be an inadequate explanation, and it seems more than likely that reservoirs of infection exist among animals in our own country.

Although Leiper[6] was able to demonstrate infection in rats at centres where trichinosis had been diagnosed in man, the general incidence of rat infection throughout Great Britain appears to be very low. The attempted detection of hitherto unrecognized endemic areas through the examination of rat carcases appeared therefore to be an unpromising line of research, and it was thought that the examination of the carcases of rat-eating animals might be more likely to produce a result, as their skeletal muscles would present evidence of trichinosed flesh having been eaten at any time during their whole lives. Some 636 stoats, 78 weasels and 2 polecats were secured for this purpose, through the medium of the pest officers in various counties, and were subjected to a thorough examination. In this process

portions of the masseter muscles, intercostal muscles, tongue, muscles of the hind leg and the whole of the diaphragm were examined as crush preparations under the microscope. The rest of the muscle was then cut off the bones and subjected to peptic digestion and afterwards examined, but the whole laborious and malodorous process was carried out without revealing the presence of a single larva of *Trichinella spiralis*.

The carcases received for examination came from the following counties: Northumberland 11, Cumberland 74, Westmorland 39, Lancashire 148, Yorkshire 42, Cheshire 6, Lincoln 106, Flint 2, Nottingham 21, Leicester 1, Shropshire 4, Warwick 1, Worcester 15, Rutland 1, Northampton 3, Huntingdon 4, Cambridge 3, Norfolk 29, Suffolk 8, Oxford 8, Hereford 2, Gloucester 26, Berkshire 2, Buckingham 15, Bedford 1, Hertfordshire 2, Surrey 1, Hampshire 17, Wiltshire 5, Dorset 12, Somerset 1, Devon 2, Isle of Wight 2, Caernarvon 52, Montgomery 3, Radnor 3, Pembroke 1, Glamorgan 2 and Carmarthen 5. (The uneven distribution of the animals does not in any way reflect their distribution throughout the country as a whole, but only the facilities at the disposal of the various pest officers.)

Experimental feeding of trichinosed flesh to ferrets, which animals are believed to be domesticated polecats, showed that infection very readily occurred. The mink is also known to be very susceptible, and there is every reason for believing that were trichinosis at all prevalent among the rats in any district from which wild mustelids were examined, the larval parasites would have been found. It is unfortunate that we were unable to secure stoats or weasels from any of the regions in which trichinosis had recently appeared in man; but even in the absence of this positive control to the observations, it is considered that the negative findings in 716 small Carnivora from so many widely distributed parts is a useful indication of the sparse distribution of *Trichinella spiralis* throughout England, and suggests that reservoirs of infection are confined to a few relatively small areas.

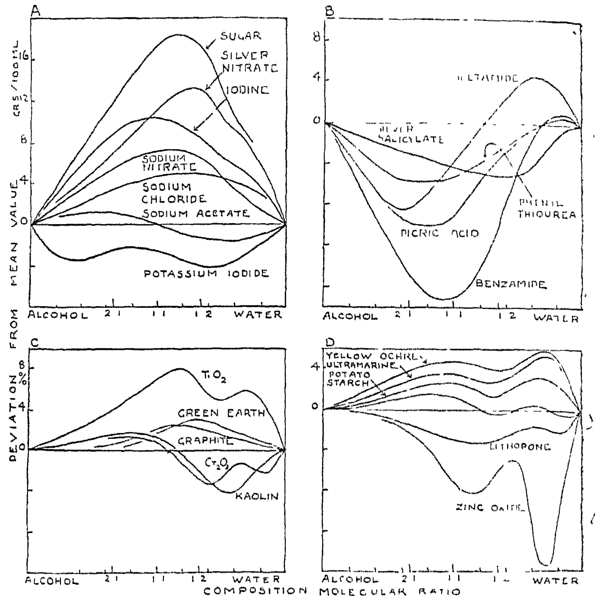
Flocculation in Solutions and Suspensions

FLOCCULATION in suspensions of finely divided solids in liquids can be readily demonstrated either by microscopic examination or by experimental methods; flocculation is mainly the cause of anomalous viscosity behaviour and thixotropy.

Solute particles, whether of sodium chloride, mercuric bromide, soaps or shellac, appear also to be aggregated in some circumstances, and this is demonstrated by comparing the properties of the solutions with those of the suspensions, especially in mixed liquids. The degree of flocculation of a suspension can be gauged by the ultimate sediment volume and rate of sedimentation, flocculation being associated with a large sediment volume and a relatively high rate of sedimentation. In the accompanying graphs



RELATION BETWEEN DEVIATIONS FROM MEAN SOLUBILITY AND SEDIMENT VOLUME (ORDINATES) AND MOLECULAR COMPOSITION (ABSCISSÆ) FOR SOLUTIONS AND SUSPENSIONS IN ALCOHOL - WATER MIXTURES.

are compared, for solutions and suspensions in ethyl alcohol – water mixtures, the deviation below the mean solubility value of several crystalloids and the deviation above the mean value of sediment volumes of several finely divided pigments. The shapes of the curves are similar, there being a maximum deviation in the neighbourhood of the composition two molecules water, one molecule alcohol.

The specific viscosity of salt solutions, colloidal solutions and suspensions alike varies with the viscosity of the liquid medium, being lower in liquids of low viscosity than in viscous media[1]. The specific viscosity of solutions of mercuric salts, aluminium chloride, sodium chloride, etc., and of suspensions of zinc oxide, titanium oxide, etc., in alcohol increases with addition of water following the increased viscosity of the medium.

The explanation of this behaviour that the higher specific viscosities are due to the longer times of orientation of asymmetric particles in the more viscous liquids can be amplified by assuming the presence of flocks which tend to orientate and break up in the stream of flow. Flocculation, akin to the sol $\rightleftharpoons$ gel transition, is a kinetic process, the solvated particles on collision tending to aggregate momentarily at least. In liquids of higher viscosity the particles moving more slowly and with a kinetic energy less in proportion to the increase in viscosity are less likely to disengage themselves from the cohesive force after collision.

With colloidal solutions of cellulose derivatives, proteins, resins and other large-molecule substances in mixed liquids, it is usually found that above a certain concentration the optimum solvent mixture yields solutions of minimum viscosity, and Palit[2] has shown that these are affected less by temperature than those in other mixtures. With the optimum solvent mixture there is a nearest approach to a solution of single molecules, which is less affected by temperature than mixtures containing higher proportions of flocculated particles. Palit, from his work on shellac, has expressed the view that the explana-

tion of the viscosity behaviour in mixed liquids has its roots in the gelation (flocculation) capacity of the system, and such solutions above the minimum gelation concentration may be regarded in a limited sense as incipient gels. In other words, in solutions of some concentration and in the poorer solvents, such as, for example, in the mixture two molecules water one molecule alcohol, the solute molecules are to a greater or less extent in an aggregated state.

Singlet Terms in the Spectrum of Molecular Nitrogen

IN recent papers communicated at about the same date, one of us[1] has reported a number of singlet band systems in the absorption spectrum of nitrogen in the extreme ultra-violet, while the other[2] has given details of several singlet systems obtained in emission in the near ultra-violet. These two sets of systems do not have any electronic levels in common as they are of different symmetry, but unfortunately the same letters have been used by both of us in designating some of the electronic states.

To avoid confusion, we suggest that primes be affixed for the upper states p, q, r, s and t of the new emission systems, while the lower level of the Fifth Positive (van der Ziel) system and of Kaplan's systems be designated a' instead of v. (a' and a would then occupy a position roughly analogous to that of b' and b.) We shall also refer to state o' as o (without prime), as it is now[1] scarcely necessary to emphasize its distinction from an earlier, but discarded, o grouping.

The known singlet states of molecular nitrogen are listed here using the revised notation. For convenience we include an abbreviated table of the most important constants, in which some of the values have been slightly 'rounded'. The vibrational constants of the normal state, and ν_0 for $a^1\Pi$ and $b'^1\Sigma$ are from Birge and Hopfield[3]. The value for B_0 of $X^1\Sigma$ has been discussed previously (ref. 1, footnote 37). Levels g, f and h, which may not all be separate states[1], have been extrapolated from measurements by Watson and Koontz[4]. The constants for b' are from Tschulanowsky[5]; for other states designated by primes and for a, w, x and y, they are derived from a study of emission systems in the near ultra-violet[2]. Absorption systems in the far ultra-violet provide slightly less accurate data for the remaining states[1]. Values of B and ω enclosed in parentheses correspond to the stronger absorption bands of a v'-progression for which the (0, 0) band was probably not observed; they are presumed to be associated with levels for which $r'_{\min.} \sim r_0''$. In these cases, estimated potential minima ($\sim \nu_e$) are given[1].

The apparent absence of absorption to levels x and y makes it likely that these states are of g symmetry. State a' would then be of type $^1\Sigma_u^-$, and would probably correspond to one of this character predicted on theoretical grounds, namely, by addition of a $\sigma_g 2p$ (that is, anti-bonding $v\pi$) electron to the low-lying $^2\Pi_u$ state[6] of N_2+. Level a' would then be metastable, irrespective of whether it lies above or below $a^1\Pi_u$, and may thus be of importance in the formation of active nitrogen.

The Black Redstart

IN his interesting article on the black redstart in NATURE of May 27, Mr. Fitter says that it "was not known to breed anywhere in the British Isles before 1923". It is well over forty years ago that I watched a pair of these birds throughout their nesting activities at Bush Hill Park, near Enfield in Middlesex. I regret that in the end I took the clutch of four eggs. These eggs were sold at Stevens' auction on July 16, 1918 (Sale No. 12,981, Lot 53) on my leaving England and after this interval I can give no more precise data.

RADIOCHEMISTRY OF AQUEOUS SOLUTIONS

By DR. JOSEPH WEISS
King's College, University of Durham

IN a recent review of radiochemical reactions, that is, reactions induced by α-particles and particularly by X-rays, Allsopp[1] affirms the conclusion that in gaseous systems there is a great similarity between radiochemical and ordinary photochemical processes, and that their mechanisms are essentially the same. In solutions, however, where radiochemical reactions are of far greater biological importance, the situation is still rather obscure and is dominated by the very indefinite 'activated solvent' hypothesis. In view of the more recent work of Dale[2] on the effect of X-rays on enzymes and biologically active substances in solution, the subject has become of renewed interest.

An attempt is made here to show that the abovementioned parallelism can be extended to solutions, and furthermore that all the known facts on the radiochemistry of aqueous solutions can be interpreted on the basis of known photochemical or chemical reactions in solutions.

It is clear from the outset that the same general principles must apply to solutions as to gases, and consequently the same conclusions are reached: namely, that dissociation processes (in general preceded by excitation) are the direct and chemically most important result of the irradiation[3]. The only important difference lies in the fact that in solutions the active radiation is to a very large extent absorbed by the solvent.

Let us first examine briefly the radiochemical changes produced in water, for which the 'activated solvent' hypothesis was first developed by Risse[4] and later adopted by Fricke[5].

Water is composed of hydrogen ions and hydroxyl ions and does not absorb in the quartz ultra-violet region of the spectrum. The strong absorption in the region between 1800 and 2000 A. is due to the OH^- ions[6]. It is well known from the photochemistry of ions in solutions[7,15] that the photochemical primary processes consist in the detachment of an electron and its subsequent transfer from the ion to one of the neighbouring molecules or ions (electron affinity spectrum). In the absorption of radiation by the OH^- ion it loses its electron, which will be transferred to a neighbouring H^+ ion, so that the radiochemical primary process for pure water is represented by:

$$(HO)^-H^+ + \text{radiation} \rightarrow HO + H \quad . \; . \; . \quad (1)$$

or similarly:

$$(HO)^- H_2O + \text{radiation} \rightarrow HO + H + OH^- \quad . \; . \; . \quad (1a)$$

Although there is this primary splitting into hydrogen atoms and hydroxyl radicals, in general, no appreciable decomposition of the water will be observed. The reason is that the radiochemical primary process (reaction 1) is always followed by the recombination of the decomposition products according to*:

$$H + OH = H_2O \quad . \; . \; . \; . \; . \quad (2)$$

thus restoring the initial state.

* For well-known reasons this and all the following bimolecular association reactions require the presence of a third collision partner. However, this fact is of no particular importance for the present discussion.

Recombination processes of this type are specially favoured in solutions because the dissociation products primarily formed are held together by the surrounding solvent molecules[8]. Actual decomposition of pure water can only occur in so far as the subsequent reactions, namely:

$$\text{(Hydrogen formation)} \quad 2H = H_2 \quad . \; . \; . \; . \quad (3)$$

and

$$\text{(Oxygen formation)} \quad 2OH = H_2O + O \quad . \quad (4)$$
$$2O = O_2$$

can compete with the reverse reaction (2).

It is conceivable that a very small decomposition of pure water into hydrogen and oxygen molecules can occur under certain conditions; for example, if the hydrogen and hydroxyl fragments are formed with a very high kinetic energy and thus quickly removed from each other's sphere of action.

However, the situation is radically changed if there are present in the water substances which can interact chemically with the hydrogen atoms and hydroxyl radical primarily formed.

Both the hydrogen atoms, as free atoms, and the hydroxyl free radical are extremely reactive. The hydroxyl radical is a strong oxidizing agent which by accepting an electron is transformed into the OH^- ion, whereas the hydrogen atoms are powerful reducing agents. There are, therefore, scarcely any substances which, if dissolved in the water, will not be attacked by these powerful reagents and will thus act as acceptors towards one or the other of the radicals formed by the irradiation. The 'acceptor action' of different solutes is now a chemical matter and it will be discussed in the following for a few cases which have been investigated experimentally.

Molecular oxygen.

$$\text{Acceptor action:} \quad H + O_2 = HO_2 \quad . \; . \; . \; . \quad (5)$$

followed by

$$\text{hydrogen peroxide formation} \quad 2HO_2 = H_2O_2 + O_2 \quad . \; . \quad (6)$$

Reactions (1) and (2) account for the fact that water is not decomposed by X-rays in the absence of dissolved oxygen. While in the presence of the latter, one gets hydrogen peroxide simply because the hydrogen atoms are removed from the solution by reacting with oxygen molecules according to the well-known reaction (5)[9], which eventually leads to the formation of hydrogen peroxide, reaction (6). The remaining hydroxyl radicals from reaction (1) will then give molecular oxygen (reaction 4), which also enters into the process.

Hydrogen peroxide. Hydrogen peroxide—either formed from molecular oxygen, or starting with a solution of hydrogen peroxide in water—is not stable under these conditions because it can itself act as an acceptor for hydrogen atoms and hydroxyl radicals, as is well known from the thermal (catalytic) and photochemical decomposition of hydrogen peroxide[10]. These reactions are:

$$H_2O_2 + H = H_2O + OH \quad . \; . \; . \; . \; . \; . \quad (7)$$
$$H_2O_2 + OH = HO_2 + H_2O \quad . \; . \; . \; . \; . \; . \quad (8)$$
$$H_2O_2 + O_2^- = O_2 + OH + OH^- \quad . \; . \; . \quad (9)$$

where reactions (8) and (9) represent the well-known chain reactions[10]. It is clear that the interplay of the radicals H, OH, HO_2 (reactions 7, 8 and 9) will eventually lead to a stationary (maximum) concentration of hydrogen peroxide in the solution. This maximum concentration, because of reaction (9)—where the anion O_2^- of HO_2 enters—

will depend on the pH, alkaline pH favouring a lower stationary H_2O_2 concentration[11].

Iodine or bromine ions[12].

Acceptor action : $I^- + OH = I + OH^-$ (10)

Reaction (10), by eliminating the hydroxyl radicals, frees the hydrogen atoms, which will give molecular hydrogen. The iodine (or bromine) atoms combine to give molecular iodine (or bromine)

according to : $2I = I_2$ . . . . . . (11)

Reaction products : hydrogen, iodine (or bromine).

At alkaline pH, molecular bromine and iodine are to some extent converted into their oxy-acids. These oxy-acids are oxidizing agents and will act as acceptors towards the hydrogen atoms. In this way the hydroxyl radicals will become free and this will result in the formation of molecular oxygen according to reactions (4).

Ferrous salts[13].

Acceptor action : $Fe^{2+} + OH = Fe^{3+} + OH^-$ . . (12)

Reaction (12) frees the hydrogen atoms formed in the radiochemical primary process, which will then give molecular hydrogen (reaction 3). Reaction products : ferric salt, hydrogen.

Ceric salts[14].

Acceptor action : $Ce^{4+} + H = Ce^{3+} + H^+$ (13)

This frees the hydroxyl radicals, which will give rise to the formation of molecular oxygen (reactions 4).

Reaction products : cerous salt, oxygen.

It is clear that this can be extended also to any other substance. In general, if the solute has oxidizing qualities (for example, potassium permanganate, etc.), it will react with the hydrogen atoms and leave the hydroxyl radicals to form molecular oxygen[12,14]; on the other hand, if the solute has reducing properties, it will be oxidized by the hydroxyl, and the hydrogen atoms will give molecular hydrogen.

In the case of more complex organic molecules (for example, tyrosin enzymes, proteins) there will always be a reaction of the solute with the hydroxyl radicals (possibly also with hydrogen atoms) which will lead to its decomposition and deactivation. If no hydrogen or oxygen gas is evolved, one has to assume that both the radicals primarily formed have reacted with the solute.

Some quantitative relationships can be derived from the mechanism proposed above. In the simplest case, the radiochemical primary process (reaction 1) is followed by either recombination (reaction 2), or by an acceptor reaction of the general type :

$$S + OH \xrightarrow{k_S} \text{reaction products} \quad . \ . \ . \ . \quad (14)$$

where S represents a general solute acceptor molecule or ion. The rate of disappearance of the solute for the stationary state $\left(\frac{d\,[OH]}{dt} = 0\right)$ is then given by the equation :

$$-\frac{d(S)}{dt} = \frac{\varkappa\, k_S\, R_{abs.}\,[S]}{k_2\,[H] + k_S[S]}, \quad . \ . \ . \ . \ . \ . \quad (15)$$

where k_2 and k_S are the rate constants of reactions (2) and (14), and $R_{abs.}$ denotes the total radiation absorbed per unit of time ($\varkappa$ proportionality factor ; brackets represent, as usual, concentrations in gm. mols per litre).

If $k_2[H] < k_S\,[S]$, ... (16)

that is, if the reaction with the substrate is rapid compared with the reverse process (2), this simplifies to :

$$-\frac{d(S)}{dt} = \varkappa R_{abs.} \quad . \ . \ . \ . \ . \ . \ . \ . \ . \ . \quad (17)$$

and

$$\Delta(S) = \int_0^t \varkappa\, R_{abs}\, dt = \varkappa\, R_{abs.}\, t. \quad . \ . \ . \quad (17a)$$

If relation (16) holds (which is probably usually the case) the total amount of solute changed $\Delta(S)$ is independent of its concentration and proportional to the total radiation dose ($R_{abs.}$) as seen from equation (17*a*). Whereas the latter is practically always true, the independence of the concentration depends on whether equation (16) is fulfilled.

The above result is in agreement with the experimental evidence[1], and in particular with Dale's 'dilution effect', that is, the radiochemical deactivation of enzymes is independent of their concentration.

If there are two solutes present, for example, in addition to a substrate S an enzyme E, the primarily formed OH hydroxyl radicals will also react with the latter in a reaction of the same type, namely :

$$E + OH \xrightarrow{k_E} \underset{\text{(deactivation)}}{\text{decomposition products}} \quad . \ . \quad (18)$$

From this, the rate of deactivation of E (for the stationary state) is given by :

$$-\frac{d(E)}{dt} = \frac{\varkappa\, R_{abs}}{1 + k_S[S]/k_E\,[E]}; \quad . \ . \ . \ . \quad (19)$$

that is, the rate of deactivation is *decreased* with increase of the ratio of the concentrations $[S]\big/[E]$. This corresponds to Dale's 'protection effect'[2].

This treatment can easily be extended to the case of several solutes : the reactivity of any particular substance being expressed by the rate constant of its acceptor reaction.

If the hydrogen atoms react instead of the hydroxyl radicals, the situation is obviously quite similar.

Apart from this indirect action of the solute as acceptor towards the radiation products hydrogen atoms or hydroxyl radical, there is, of course, also the possibility of a direct absorption of the radiation by the solute itself followed by some chemical change.

Any photochemical or chemical primary process in solution consists in either the removal or the transfer of an electron, and these processes constitute the two general types of chemical elementary processes (oxidation and reduction). Whether these processes are induced directly by the radiation or through reactions with hydroxyl radicals (oxidizing, electron acceptor) or hydrogen atoms (reducing, electron donor) makes no difference for the final result.

This conclusion is fully borne out by a consideration of those solutes of which the photochemistry is fully known, as is the case, for example, for the simple inorganic ions[15] which have been discussed above. A closer study shows that in these cases it would make no difference for the end effect whether the radiation acts directly on the solute or indirectly through the primary decomposition products of the water. It is obvious that this fact alone would make the radiochemical change independent of the concentration in the case of one solute.

In aqueous solutions it may be said that, in general, whether the action of the radiation on the solute is

either direct or indirect, there will be no appreciable difference in the qualitative result of the radio-chemical process. However, the difference in the quantitative result may be of great importance from a biological point of view*. Furthermore, it is clear that the general principles outlined above can also be applied to non-aqueous solutions.

* This was very kindly pointed out to me by Dr. W M Dale.

FREEDOM FROM WANT OF FOOD

A PUBLIC conference on "Freedom from Want of Food" was organized by the Watford branch of the Association of Scientific Workers and other local bodies on May 20 to discuss the findings of the United Nations Conference on Food and Agriculture held at Hot Springs, Virginia, last year.

Sir Jack Drummond, of the Ministry of Food, who was one of Great Britain's delegates to Hot Springs, described that meeting as the first conference of the peace. It was concerned with the international planning of the production and distribution of food. Forty-four nations were represented and there were scarcely any conflicting views among the delegates. Scientific men considered how their knowledge of nutrition could be applied to the vast problem of malnutrition; agriculturalists considered how best to produce the vast quantities of food the world requires for the adequate nutrition of all; economists considered how the world's trade could be planned to facilitate the most efficient production and distribution of food. Finally, the findings of these several groups was co-ordinated into the United Nations plan for securing 'Freedom from Want'. By international agreement and planning the nations were to produce and distribute food on the basis of physiological requirements.

The problem, Sir Jack said, is terrifying in its magnitude. For example, in culturally backward countries, better nutrition would result in a vastly better survival-rate of children. Hence populations already numerous would only add to their number and thus aggravate the already terrible problem of adequate food supply. In Britain we have made a start in the rationalization of food distribution. Milk was in short supply in the winter now not because it is being produced in lower quantities than before the War. Actually far more milk is being produced, but it is being allocated to those who need it most —nursing mothers and children. Food—the right kind of food—is now regarded as a very important part of preventive medicine. Medical men are becoming more and more interested in how to prevent disease rather than merely how to cure it. Nutritious food is a great preventative of illness.

Mr. P. Lamartine Yates said that four things are necessary in order that practical results should come out of the deliberations at Hot Springs. First, there must be constant surveys into the state of the nutrition of the people and inquiry into what foods are being eaten. Since the War, the Ministry of Food has made surveys and so has its opposite number in the United States. As a result, a great deal of information on diet and nutrition has become available. These surveys must continue after the War if malnutrition is to be avoided. Secondly, propaganda such as that started by the Ministry of Food to show people what they ought to eat and how they can get the best out of their food should be continued and extended. Thirdly, there must be a stable relationship between wages and the cost of food. Poverty is the basis of malnutrition and at present food prices are being kept down by means of a Government subsidy of £200 million a year; this is at 2*s.* a person a week. While Mr. Yates is not in favour of the continuance of such vast subsidies after the War, he thinks that wages and food prices should fluctuate together.

Finally, Mr. Yates urged that someone must be responsible for looking after all this. The United Nations are setting up a permanent international committee in Washington; but on a national scale Mr. Yates believes that a Ministry of Food will still be necessary. We are in for a grim time after the War. Shipping is short and because labour all over the world is engaged in war production there is a world food shortage. Only with difficulty will the United Nations obtain sufficient food to alleviate the worst sufferings of a battered and starving Europe. We must be prepared to put up with rationing of our basic food for a year or two after the War.

There followed a lively discussion and several important points were raised from the floor.

The Conference unanimously adopted a resolution urging that similar conferences should be organized in other parts of Britain to make known to the public the resolutions passed at the Hot Springs Conference. The necessity was accepted for continued rationing of food in Great Britain until such time as the population of Europe is ensured of adequate nourishment, and it was resolved that the administration of relief to enemy occupied countries should not be used either directly or indirectly as a means of exerting political pressure upon the populations concerned.

FOOD PRODUCTION IN INDIA

IN his presidential address to the Section of Agriculture at the thirty-first Indian Science Congress, Rao Bahadur Dr. D. V. Bal presented certain aspects of the present and post-war food production in India.

One of the paramount needs of India at the present time is to lessen the gap between the food produced in the country and the amount required to feed the population adequately. Before the War, home production fell far short of requirements and 2–2·6 million tons were imported annually. The population of India is now much larger than it was a few years ago, but the increase in the area under food crops and normal yields have not been proportionate to the increase in population. The resultant food shortage and occasional famines indicate the urgency of

the need to make India self-sufficient for food, instead of relying more and more upon imports.

To effect this, many factors require consideration, and State aid in various directions is essential. Water shortage can be mitigated by irrigation facilities and by the construction of wells in certain areas. Low yields are often due to the selection of unsuitable types of soil for certain crops. Surveys need to be undertaken to adjust this problem, and to determine where poor arable land would be more profitable if it were laid down to pasture or trees. Soil fertility can be improved by raising the organic matter status by encouraging the preparation of composts from farm wastes, town refuse and night soil. Rotation of crops, including the cultivation of legumes, would serve the double purpose of providing valuable essential foodstuffs and raising the nitrogen content of the soil. The available amount of protein for human consumption is definitely inadequate, and the deficiency can only be made good by extensive growth of leguminous crops.

It is calculated that improvement in the quality of the seed sown would result in an increase of 10–20 per cent of crop, and a great extension of seed farms is called for to produce and distribute improved seeds of various crops. The breaking up of fallow land to increase the arable acreage is not always practicable, owing to the need for maintaining adequate pasturage for cattle, which in India are so important as beasts of burden as well as for milk production. Serious attempts are being made to improve the cattle by better methods of breeding, and a necessary corollary to this is a stepping-up of the amount and quality of the available feed. As it is, the existing supplies of fodder and the area under pasture are inadequate, and to avoid the inevitable competition between the utilization of land for human and for cattle food, it is essential for better methods of cultivation and manuring to be adopted in both cases. If this were done, an increase of 25–33 per cent of human food could be produced from the area at present under the plough, while adequate manuring and appropriate systems of grazing would bring about a corresponding improvement in the supplies for cattle.

Very considerable losses occur in stored grain from weevil attack, at least 1·3 million tons a year being damaged by insects. Rats and spoilage by weather cause further loss, and provision is needed for more adequate storage facilities.

If maximum crop production is to be obtained, it will be necessary for the State to play a part by subsidizing the cultivators, in order to encourage them to use modern methods without the fear of financial loss. The more adequate food supplies thus obtained would so improve the health and strength of the workers as to raise the standard of industrial manufacture as well as that of agriculture.

In order to stabilize the production in India of various crops in general, and food crops in particular, it is essential to consider the long-range problems and prepare a co-ordinated plan to make the country a self-sufficient unit. Experiments are necessary to determine the maximum crop-yielding capacities of soils, special attention being given to the organic matter and nitrogen status of the soils. The standard experiments finally fixed should be conducted simultaneously at various places with different soils and climatic conditions. For this purpose an efficiently trained body of workers is essential, partly to carry out the fundamental research and partly to act as propagandists in making the results known to the agriculturists. After the return of personnel and machinery from war purposes, many men can be used to colonize selected areas and to carry out organized campaigns against diseases and pests of crops, involving the use of specialized machinery, insecticides and fungicides. Many war vehicles could likewise be adapted for power work on the farm for many purposes.

Finally, it is realized that a suitable wage system must be evolved, ensuring a basic wage to the agricultural labourers, rising in accordance with increased costs of living. Such a system, together with certain subsidies to the cultivators, would make for financial stability in the agricultural world.

BIOLOGY OF THE PRAWN LEANDER

LITTLE is known in detail of the habits of the prawns of the genus Leander, and Dr. H. Höglund's monograph* fills a distinct gap. It is an excellent work and a model for those dealing with the biology and life-history of a single species of prawn. *Leander squilla* together with the more important *Leander adspersus* forms a fishery on the west coast of Sweden. The researches have been carried out, partly as field investigations in order to study *Leander squilla* as a member of a stock, its habits, propagation, growth, etc., under natural conditions in the sea, partly as aquarium experiments in order to study such individual processes as mating, spawning, hatching and moulting.

During the winter, the prawns inhabit deep water. When the water in the upper layers has become warmed in the spring, they begin to appear on the shores, and breeding takes place throughout the summer. Temperature is shown to be all-important to migration, breeding and growth, and the time of arrival of the prawns on the shores varies in different seasons according to conditions. In the autumn they return to deep water. Unlike *Leander adspersus*, which, according to Mortensen (1897), migrates to deeper and colder water to hatch out the larvæ, *Leander squilla* apparently remains close to shore in shallow water. The newly hatched larvæ occur in the plankton. It is specially to be noted that the larvæ of both the Leander species occupy the upper layers, whereas all the other carid larvæ of the district frequent the deeper water from 15 to 25 metres.

Both males and females become mature during their second summer, when about a year old. Females may produce two broods in one summer. Larger and older prawns are scarce, but these avoid the nets much more successfully and there is evidence that they may live for three years.

Striking film photographs are given of the pairing, moulting and spawning processes taken in aquaria. The armature of the female thorax and pleopods in the breeding season ("the breeding dress") is very fully investigated and the exact function of each batch of setæ is determined. Most of these setæ are for use only when the eggs are extruded, appearing at the moult preceding spawning and disappearing after the last batch of eggs has hatched out, when another moult takes place.

* "On the Biology and Larval Development of *Leander squilla* (L.) forma *typica* de Man." By Hans Höglund. *Svenska Hydrografisk-Biologiska Kommissionens Skrifter*, Ny Serie, Biologi, **2**, No. 6 (Stockholm, 1943).

The larvæ of *Leander squilla* forma *typica* are described in detail and closely resemble those of *L. adspersus*, although the colour is quite different. Five or six larval stages are recognized, the last stage changing to post-larva. The larval characters of the two species are compared in a table. The whole planktonic larval period lasts for about four weeks, after which the post-larvæ make their way to the shores. This they do very quickly, often before another moult takes place, and the young prawns appear on the shores in enormous quantities.

The illustrations throughout are very good, including clear outline figures in text and plates. The photographic film figures are very illuminating.

FORTHCOMING EVENTS

Saturday, June 17

BIOCHEMICAL SOCIETY (in the Physiology Department, University College, Dundee), at 2 p.m.

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (at Neville Hall, Newcastle-upon-Tyne), at 2 p.m.—Mr. H. R. Wheeler: "American System of Coal Mining"; Messrs. R. Williams, W. Jeffery and A. Taylor: "Outbursts of Gas from the Floor of Coal Seams", Part 1.

Monday, June 19

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 3 p.m.—Annual General Meeting.

ASSOCIATION OF AUSTRIAN ENGINEERS, CHEMISTS AND SCIENTIFIC WORKERS IN GREAT BRITAIN (at the Institution of Mechanical Engineers, Storey's Gate, St James's Park, London, S.W.1), at 7.15 p.m. —Prof. P. H. Gross: "Planning and Education for Technical Research".

Tuesday, June 20

SCIENTIFIC INSTRUMENT MANUFACTURERS' ASSOCIATION (at the Waldorf Hotel, Aldwych, London, W.C.2), at 1 p.m.—Luncheon Meeting. Mr. J. Chuter Ede, D.L., M.P.: "Technical Education".

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. R. J. E. Silvey: "Listener Research".

Wednesday, June 21

ROYAL SOCIETY OF MEDICINE (joint meeting of the SECTION OF COMPARATIVE MEDICINE with the INSTITUTE FOR THE STUDY OF ANIMAL BEHAVIOUR) (at 1 Wimpole Street, London, W.1), at 2.30 p.m. —Dr. C. S. Myers, F.R.S.: "Instinct"; Dr. W. H. Thorpe: "Learning Processes in Animals"; Prof. D. B. Johnstone-Wallace: "Grazing Habits of Beef Cattle"; Dr. Arthur Walton: "Comparative Sexual Behaviour in the Male".

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Scientific Papers.

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 4.30 p.m.—Mr. N. Carruthers: "A Simple Periodoscope for Meteorological Data". Dr. T. E. Allibone: "Multiple Lightning Strokes".

ZOOLOGICAL SOCIETY OF LONDON (at Regent's Park, London, N.W.8), at 4.30 p.m.—Exhibition of a Cinematograph Film of some Animals taken in the Society's Gardens, with Commentary by Dr. Edward Hindle, F.R.S.; Mr. Michael Pease: "The Cambridge Auto-sexing Poultry Breeds".

Saturday, June 24

ASSOCIATION FOR SCIENTIFIC PHOTOGRAPHY (joint meeting with the SCIENTIFIC FILMS ASSOCIATION) (at the Large Theatre, Ministry of Information, Malet Street, London, W.C.1), at 3 p.m.—Discussion on "The Construction and Presentation of Scientific Films". (Mr. Arthur Elton: "The Scope and Distribution of Scientific Films"; Mr. Geoffrey Bell: "Shooting Scientific Films"; Dr. J. Yule Bogue: "The Production of Scientific Films for Medical and Biological Purposes".)

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN ENGINEERING in West Africa—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.836A) (June 21).

PHYSICIST for essential War work (work would include experience in various research departments of a North London firm specializing in optical instruments for scientific and industrial research and control)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. A.518XA) (June 21).

LECTURER (woman, resident) in BIOLOGY at the Cheshire County Training College, Crewe (for Women students)—The Director of Education, County Education Offices, City Road, Chester (June 22).

GRADUATE LECTURER IN GENERAL SCIENCE—The Principal, Derby Technical College, Normanton Road, Derby (June 23).

LECTURER IN ELECTRICAL MACHINERY in the Department of Electrical Engineering—The Registrar, King's College, Newcastle-upon-Tyne 2 (June 24).

TEACHER (full-time) OF GENERAL SCIENCE with qualifications in PHYSICS and CHEMISTRY, in the Junior Technical School of Oldham Municipal Technical College—The Director of Education, Education Offices, Oldham (June 24).

ASSISTANT MASTER to take ENGINEERING SUBJECTS (Mechanical or Electrical), with subsidiary Mathematics or Drawing, an ASSISTANT MASTER to take PRODUCTION ENGINEERING Subjects, with Workshop Practice, and an ASSISTANT MASTER to take MATHEMATICS and SCIENCE, with subsidiary Drawing—The Principal, Enfield Technical College, Queensway, Enfield, Middlesex (June 24).

MASTER or MISTRESS to teach MATHEMATICS in the Mid-Essex Technical College—Mr. E. W. Alston, Education Office, Mid-Essex Technical College, Chelmsford (June 24).

PSYCHIATRIC SOCIAL WORKER with qualifications in SOCIAL SCIENCE and MENTAL HEALTH—The Director of Education, Education Offices, Middlesbrough (June 24).

EDUCATIONAL PSYCHOLOGIST (man or woman)—The Director of Education, Education Offices, Wolverhampton (June 24)

AGRICULTURAL CHEMIST—The Director of Agriculture, School of Agriculture, Houghall, Durham (June 24).

HORTICULTURAL ASSISTANT (temporary, male or female)—The Clerk to the County Council, County Offices, Sleaford, Lincs. (June 24).

LECTURER IN MECHANICAL ENGINEERING, and a LECTURER IN MATHEMATICS, in the Denbighshire Technical College—The Director of Education, Education Offices, Ruthin, Denbighshire (June 26).

LECTURER (temporary) IN MATHEMATICS—The Registrar, King's College, Newcastle-upon-Tyne 2 (June 26).

ENGINEER AND WORKS MANAGER of the Great Berkhamsted Waterworks Undertaking—The Acting Secretary, Great Berkhamsted Waterworks Co., 166 High Street, Berkhamsted (June 30).

SENIOR LECTURER IN SCIENCE with Graduate or equivalent qualifications in PHYSICS and CHEMISTRY, in the Ipswich School of Technology —The Secretary for Education, 17 Tower Street, Ipswich (June 30).

COMBUSTION AND RESEARCH ENGINEER by large organization, with headquarters at Glasgow—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2031XA) (July 1).

ASSISTANT LECTURER IN ENGINEERING—The Registrar, The University, Manchester 13 (July 1).

MECHANICAL ENGINEER (with general experience and good Degree) for Research and Development in Steel Tube Industry (Midlands)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2162XA) (July 3).

SENIOR ASSISTANT DRAINAGE AND IRRIGATION ENGINEER (Reference No E.902A), and a JUNIOR ASSISTANT DRAINAGE AND IRRIGATION ENGINEER (Reference No. E. 903A), by the Sierra Leone Government —The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting appropriate Reference No.) (July 5).

EXECUTIVE ENGINEER by the Sierra Leone Government—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.1011A) (July 5).

TECHNICAL CHEMIST (Reference No. F.2012XA) and a LABORATORY ASSISTANT (Reference No. F.2503XA), by London Paint Manufacturers —The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting appropriate Reference No.) (July 8).

ASSISTANT SECRETARY to the Oxford and Cambridge Schools Examination Board—The Chairman of the Oxford Delegacy, St. Catherine's Building, St. Aldate's, Oxford (July 31).

READERSHIP IN PHYSICAL ANTHROPOLOGY—The Registrar, University Registry, Oxford (August 31).

ASSISTANT LECTURER (Grade III) IN THE DEPARTMENT OF ORGANIC CHEMISTRY—The Registrar, The University, Liverpool.

PSYCHIATRIC SOCIAL WORKER (full-time)—The Secretary, Education Office, Trinity Street, Colchester.

TEACHER OF MATHEMATICS AND PHYSICS in the Handsworth Technical College and Junior Technical School—The Principal, Handsworth Technical College, Golds Hill Road, Birmingham 21.

TEACHER OF SCIENCE (particularly CHEMISTRY) AND MATHEMATICS, and a TEACHER OF MATHEMATICS AND ENGINEERING SUBJECTS, in the Slough Junior Technical and Commercial School—The Secretary for Education, County Offices, Aylesbury, Bucks.

GRADUATE LECTURER IN SCIENCE AND MATHEMATICS—The Clerk to the Governors, Technical College, Chesterfield.

TEACHER (temporary) OF CHEMISTRY and/or PHYSICS, with subsidiary MATHEMATICS, in the Swansea Technical College—The Director of Education, Education Department, Guildhall, Swansea.

GRADUATE IN PHYSICS, a GRADUATE to teach ELEMENTARY MATHEMATICS and SCIENCE, mainly for work in the Day Technical School for Boys and part-time Day Classes, and a GRADUATE to teach SCIENCE, mainly BIOLOGY, mainly for work in the Day Technical School for Girls, of the Maidstone Technical Institute—The District Secretary of the Kent Education Committee, Mr. A. W. Peacock, 13 Tonbridge Road, Maidstone.

PSYCHIATRIC SOCIAL WORKER (full-time)—The School Medical Officer, Public Health Department, County Hall, Maidstone.

RESEARCH PROFESSORSHIP IN ANIMAL HEALTH—The Principal, University College of Wales, Aberystwyth.

TRAINING OF METALLURGISTS

A CONSIDERABLE amount of attention is being given at the present time to the general problems of education and training in Great Britain, and various groups such as the physicists, chemists, etc., have been reviewing existing arrangements for their professions. Recently, the subject of the supply, training and status of metallurgists has been examined by the Council of the Iron and Steel Institute, and a report giving its conclusions has been issued*. Although the Iron and Steel Institute as a body is primarily concerned with ferrous metallurgy, many of the recommendations given in the report will be found to apply to metallurgists destined for the non-ferrous industry. The report is a comprehensive one, and will be of value to all those concerned with the recruitment of metallurgists and with their employment in industry.

A severe shortage of trained metallurgists is expected at the end of the War. Various factors have contributed to this. The science of metallurgy is relatively new ; one may recall that the primary principles involved in the heat-treatment of carbon steels were still a subject of debate at the close of the War of 1914–18, and it is only during the period between the Wars that the metallurgist, as distinct from the chemist, has won real status in industry. Coupled with this possible lack of appreciation, both the demand and the supply has been limited by the severe depressions to which the industry has been subjected. Meanwhile, great progress has been made in steel-making processes, in the development of new and stronger materials, etc., and changes in technique which involve the employment of more highly trained metallurgists. It is envisaged that continued technical development will be necessary if British industry is to thrive in the highly competitive markets of the post-war period, and thus a still higher proportion of trained men will be required.

To cope with the expected shortage, the following steps are recommended to stimulate recruitment : direct contact with schools, attractive initial salaries, good prospects, etc. It is surprising how little information the average schoolboy receives which in any way interests him in metallurgy, and consequently, except for the districts where metallurgical industries are located, a metallurgical career seldom receives consideration. Publicity of the right type will undoubtedly cure this ; but to produce permanent effects, remuneration and prospects will be expected comparable with those in other professions, and adequate to eliminate concern regarding the violent depressions suffered periodically by the industry.

The report considers the training of personnel under three main headings : university training, education below university standard, and adult training. For the university trained man, it recommends that the degree course should be divided into two parts. The first should be directed to higher study of the basic scientific subjects, physics,

* The Training of Metallurgists, with Special Reference to the Iron and Steel Industries. Pp. 32. (Iron and Steel Institute, 4 Grosvenor Gardens, London, S.W.1, 1944.) 2*s*. 6*d*.

chemistry, some mathematics, and engineering, and the second to a continuance of study in these fields and to the particular study of metallurgy. This emphasis on a high standard in the basic sciences will no doubt be given appropriate consideration by the university authorities. Great importance is attached to early experience of industrial operations during a university career, and it is suggested that works courses during vacation should form part of every university course. Careful consideration will need to be given to the extent to which such courses can be instituted without leading to 'over training' of the undergraduate.

For the training of process metallurgists, the report concludes that existing facilities are inadequate ; and it is suggested that Great Britain should legislate for training many of the men needed to develop our Empire resources. The primary metal-producing industries throughout the British Empire form a large potential market for British manufactured products, and the development and sale of such products will be facilitated if the personnel in control are British trained.

Once in the works, the training of a graduate should be continued for some years, through arrangements which permit him to work for periods in all the various departments in which he may be particularly interested. This will increase his experience, give him a grounding in the internal administration and enable his employers to form a good idea of any special aptitude he may have. Such training schemes are in progress in some of the larger organizations and are successful. Perhaps insufficient attention has been paid in the past to the latent possibilities in new employees ; thus it sometimes happens that a man is taken on for a specific job, and although he may turn out ultimately to be not specially suited for the particular work concerned, he has to continue with it ; in large organizations there are much greater possibilities for manœuvre in such matters. Employers are recommended to encourage their men to write papers, to join in discussions and pay visits, and generally to participate in the professional activities associated with their particular branch of industry. For the keen man such facilities are well worth while, since they lead to rapid development of a sound critical faculty.

The importance of postgraduate education is not sufficiently emphasized in the report. The report indeed urges the need for improved facilities, and suggests that each university should specialize in some subject appropriate to the local industry. Postgraduate research is likely to be more productive for the individual if it is carried out where there is an active 'school' of research. Under such conditions a man, merely by keeping in touch with his fellows, can get a wide knowledge of research methods, etc., in a very short time. Again, it is essential that the professor should be keenly interested in research and not weighed down with administrative duties and normal teaching. The whole subject of postgraduate research needs reviewing by the authorities, to ensure that research facilities and atmosphere are really satisfactory.

Many of the recruits to industry come direct from school, and will no doubt continue to do so for some time. Their subsequent education takes the form of part-time courses or evening classes, and suggestions for improvement are made, including the institution of courses leading to the award of a national certificate in metallurgy. Such an award would be a desirable objective for the student, and a useful qualification to the employer. The report suggests that industry should encourage part-time education and limit the attendance necessary at evening schools to the absolute minimum.

The position with regard to part-time training should be simplified when the proposal is implemented that all persons who show sufficient ability at school should automatically receive a university training. Then the amount and type of training appropriate to the remainder will be more limited in scope than at present, and may conceivably be carried out by the envisaged young people's colleges or similar institutions. It is most desirable that men with first-class ability should be saved from the onerous task of educating themselves through evening classes and of suffering from "an impoverishment of initiative and intellectual quality at a period of life critical for the full development of the powers and capacities of the individual"*. In the meantime, a broadminded attitude from industry and close collaboration with the universities and technical colleges are necessary to achieve the best results from the promising material that enters industry direct from school.

On the question of adult education, the report mentions the need for refresher courses on specialized subjects for managers and staff, and refers to short courses to be held at universities with residential facilities. The Bristol conferences on metals and the Cambridge crystallographic conferences are successful examples of such meetings held by physicists. Interchange of senior staff between university and industry is considered to be very beneficial ; but no practical methods for achieving such an interchange have yet been put forward. There are obvious difficulties, and various substitutes, such as interchange lectures and visits, probably represent the extent to which such suggestions can be implemented.

The training of workmen either for posts of higher responsibility or to give them better insight into their normal work is considered, and reference made to the outstanding success of the educational efforts of the Sheffield Trades Technical Societies. This organization works in the closest co-operation with the University of Sheffield, where lecture courses are provided "to enable workers to study the commercial and technical side of their work and to receive the latest scientific information which may be applied to their trade". Similar organizations might well be set up in other large manufacturing centres.

Satisfactory operation of all these educational schemes depends to a very large extent on the existence of the requisite number of able teachers ; and, especially in the case of part-time courses and

* See p. 8 of "Industry and Education—a Statement". From Nuffield College. (Oxford University Press, London, 1943.)

evening classes, teachers are required who can make their subject interesting. The report directs attention to an existing shortage of teachers, and suggests that both remuneration and status should be raised so that more men will become available.

Very little advice is offered regarding the selection of men to be trained. This subject should be given serious consideration. All will agree that educational arrangements should be such that every person has facilities readily available appropriate to his abilities. On the other hand, efforts made to train people beyond their capabilities are largely wasted. Many evening school candidates probably fall into this category, and some attempt should be made by means of psychological tests to restrict facilities in technical training to those persons who can benefit.

EDUCATION AND THE WORLD STATE

The World We Mean to Make

And the Part of Education in Making It. By Maxwell Garnett. Pp. 264. (London: Faber and Faber, Ltd., 1943.) 10*s*. 6*d*. net.

IN times of comparatively rapid social change, there tends to be more thinking about education than in periods of comparative quiescence. Those who seek to control the development of society, in whatever aspect of it they are interested, are apt at some stage in their thinking to see in education one of the main forces which can bring about the conditions they desire. This is natural, for one of the chief functions of education is to transmit to the young what the older members of society most value in their culture, as the basis of the new world in which the young will live. Dr. Maxwell Garnett is concerned with the world "during the next two generations", and he adopts Mr. R. A. Butler's dictum that "education is the main arm with which to win the next peace".

Dr. Garnett has a plan for education in England; but to add another to the many plans which have been published during the last few years is not the primary purpose of his book. It has been a weakness of recent planning in education that the aims of education have not usually been thought about enough or expressed explicitly enough, and with the ends obscure it has been difficult to evaluate the means proposed. It is a great merit of Dr. Garnett's book that he presents a reasoned statement of the functions and processes of education as he sees them. His aims in education are an integral part of a philosophy, and the means he proposes take cognizance of political and social trends and the evidence of psychology. Not all will agree with his philosophy or with his view of the facts, but they do constitute reasoned position which is both tenable and arguable.

A few sentences may summarize Dr. Garnett's position, though it cannot do justice to the wide range of his information and his thinking. The War should be followed by a general settlement, based upon the Atlantic Charter and President Roosevelt's four freedoms, which should bring into being an international authority, the Commonwealth of United Nations. This Society of States should promote human welfare, and should maintain the rule of right by administering international law. It should have at its command the sanction of armed force. But the Commonwealth cannot be maintained merely by the fear of power: it must depend on the enlightened loyalty of its citizens and their will to serve its purposes. Enlightenment by itself will not serve: " 'The mere intellect', wrote Aristotle, 'has no motive power' ". Free will, "something from outside space and time", "a spirit which can alter the course of our lives", will play its part, but since such interventions are comparatively rare events we cannot rely too heavily on them. We must in the main depend on the development of a 'sentiment' of loyalty to the Commonwealth as the single wide interest which will move men to act in the ways required. But are the values which the Commonwealth enshrines and which are to command our loyalty true as well as good? They appear in our inner world, "the ordered world pictured by the man with a single wide interest", as desirable ends: does our inner world correspond with the outer world, "the world as it really is, or as it is partially known to science", so that our ends can be regarded as not only good but also true? We do not know. We can only believe, by adopting a hypothesis "beyond the so-called 'discoveries of human reason' ", which we may find among "the essentially similar 'divine revelations' ". Most of the seven or eight great religions of the world offer the hypothesis that the supreme good is also the supreme reality. The Commonwealth, which must depend on the loyalty of its citizens, should therefore foster religious education. In Great Britain this means Christian education. The aims of education in England may be summed up as Christian faith, political loyalty and economic efficiency.

This is not a novel position. Dr. Garnett himself relates his ideal to that of Dr. Arnold a hundred years ago, to train Christian gentlemen. It is probably the position of a majority of those in Great Britain who are articulate about education. The plan for education which Dr. Garnett bases on it is accordingly not a revolutionary one. It resembles in many of its details the proposals of the Education Bill, which itself represents the highest common factor in the attitudes of those who have power to legislate for education. Dr. Garnett wants, for example, grammar schools, technical schools and modern schools, with some experiments in multilateral schooling. He finds good reasons why compulsory attendance should cease at fifteen rather than sixteen. He wants attendance at young people's colleges on one day a week. His plan need cause no alarm or despondency among the supporters of preparatory schools, public schools, direct grant schools, or the Oxford and Cambridge open scholarship system. He does not hesitate to apply to the schools the hypothesis he has adopted about religious truth. For example, "Local education authorities or managers will have to choose the head teachers of their primary schools from among those members of the profession who are zealous for Christian education". He refers, of course, to rights of conscience. "This practice should not be enforced by law. This is eminently a case for Plato's 'victory of persuasion over force' ". The appointing body would merely ask the prospective head-teacher certain questions, and "A candidate who gave no adequate answers to these questions or to others of the same sort would not be appointed as head teacher". In certain directions, such as adult education and the regional organization of educational administration, Dr.

Garnett would go further than Mr. Butler in his agreed measure has proposed to do. But in general, Mr. Butler could congratulate himself on finding respectable philosophical warrant for his Bill in Dr. Garnett's book, and Dr. Garnett could reflect with satisfaction that his theory of education is capable of translation into the realistic terms of administrative legislation. Their new education will be cast in the image of the old, but will undoubtedly be in many respects an improved version.

It is well that those who hope to fashion the shape of things to come should in this way draw on the wisdom that tradition and their own experience have given them. They cannot do more. Dr. Garnett's book, with its orderly argument and copious use of evidence, will help them to see their own way ahead. New generations, however, will have new experience and will interpret it in their own way. The world we mean to make will not necessarily be the world the next generations will see fit to make.

R. A. C. OLIVER.

UTILITARIAN ASPECTS OF GEOLOGY

Geology in the Service of Man

By Prof. W. G. Fearnsides and Dr. O. M. B. Bulman. (Pelican Books, A.128.) Pp. 158+8 plates. (Harmondsworth and New York: Penguin Books, Ltd., 1944.) 9*d*. net.

NOT so very long ago, the layman who wanted a simply written and up-to-date book on geology would have had to be content with a students' primer not altogether suitable for his needs. Now some half-dozen small volumes, written especially for him, await his choice; and among them this new "Pelican" book takes a high place. The authors have set out to show how geology has been used in the service of man—when he has been wise enough to utilize such knowledge—and have made clear their purpose in writing the book by their introductory note: "It is regrettable that more geologists have not been professionally associated with the war effort; it will be a tragedy if geological knowledge is not co-ordinated and directly applied in post-war reconstruction".

The book is divided into two parts, the earlier being a brief account of geological principles, an acquaintance with which is necessary for the appreciation of the later part, which is a review of the economic aspects of the science. In Part 1 the manner of treatment followed by the authors is what might be termed the 'classical' method; that is, it begins with the consideration of the earth as a globe, and the composition and physical properties of its core and crust, as elucidated by geophysical and chemical investigations. Whether or not this is a better approach for a layman than one which begins with the phenomena and materials around him—and therefore more or less familiar—and leads him to the less familiar and unknown is obviously a matter of opinion. In the present instance, however, the course taken lands him, in about six pages, in a discussion of stability relationships of mineral constituents that may deter him from going farther—which would be a pity since the problem cannot be treated with sufficient accuracy and detail to satisfy the critics, and since it appears that at the moment work on these lines has proved of limited value in petrology. If the reader skims this chapter and passes to those on the building of continents, the development of scenery and the geological history of Britain, he should feel well repaid by following a fascinating story simply told.

A short chapter on the nature and construction of geological maps concludes Part 1. Here, just enough is said to titillate the curiosity of the intelligent reader and make him wish for more, but (most importantly) enough to show that there is a more or less simple geometrical arrangement of the rocks of the crust and not a higgledy-piggledy mess as the uninitiated still seem to think.

Part 2 contains seven chapters, each dealing with an important aspect of industrial geology, such as water supply, geology and soils, petroleum, engineering geology (foundations, reservoirs, tunnels, building materials and roadstones), mineral supplies for heavy industries (coal and iron ores), non-ferrous metals and chemical supplies, and gemstones. Here, indeed, is a wealth of information to satisfy the inquirer; and, considering the scope of the subject-matter, it is noteworthy that the treatment is accurate and up to date throughout.

It may be serviceable to direct attention to a small point of nomenclature. Whereas the terms 'well-graded' and 'well-sorted' were formerly synonymous in geological writing, the practice of engineers is now to apply the former expression to a sediment in which the grains are distributed fairly evenly throughout the grades (as defined by size-limits)—that is, 'well-graded' becomes just the reverse of 'well-sorted' (where most of the grains belong to one size grade). In the interests of conformity and in order to make effective use of two good words, it would be well (at least in my opinion) for geologists to follow the engineers' practice.

To compress a large part of a text-book of geology into a "Pelican" book of 150 pages is no mean achievement. Inevitably it has necessitated a condensed style, but clarity is helped by many diagrams and a number of photographic illustrations. We may hope that the subject-matter will not prove so solid as to be indigestible to the general reader; and, if we can judge from the popularity of other "Pelican" books, certainly not less condensed and even more technical, it should not do so. As it takes two to make a bargain, it would seem that the layman, as well as the man of science, is now playing his part in helping forward this method of disseminating knowledge.

P. G. H. BOSWELL.

WEATHER WISDOM

Weatherwise

England's Weather through the Past Thirty Years. By John H. Willis. Pp. 110+30 plates. (London: George Allen and Unwin, Ltd., 1944.) 7*s*. 6*d*. net.

MR. JOHN H. WILLIS is a member of the band of amateur meteorologists who co-operate with the Meteorological Office in maintaining local records of weather according to a fixed plan day by day and year by year. The climatology of Great Britain owes much to their efforts, which are purely voluntary. It will easily be realized that to carry out such a self-imposed duty successfully, a man must be an 'amateur' in the literal sense of the term. Observations must be made in all weathers; they must take priority over personal convenience, they must be made punctually and they must be meticulously

recorded. So much is stated in the official pamphlet of 'requirements'. Here we may go further and say that the observer must have a real love of Nature, as expressed in the changes of weather. The daily reading of the instruments must not be merely a task to be done; it must be something which he loves to do, and which he approaches with a sense of adventure.

Mr. Willis's pleasant little book is the product of this attitude of mind, a sort of cavalcade of the years and the seasons as they presented themselves during a period of thirty years to an interested onlooker. Starting with the year 1913, we have a summary, on the scale of four or five pages to each year, of what the weather was like at Southwell Lodge, Norwich, with such few actual figures as are necessary to give precision to the verbal picture. In style, the author inclines to the poetic rather than to the scientific, "—a queenly June ascended her throne, to banish from her realm a measure of the month's rainfall, and dower the period of her reign with an additional hour of daily sunshine" (1914). A trifle 'twopence coloured' perhaps, but it is well to remember that a sequence of 'penny plain' statements like "June was dry and sunny" can be deadly dull.

Here and there the story is interlarded with snippets of meteorological theory, not all of which will find favour among the professionals. There are some remarks, too, about popular weather maxims. One of these calls for comment. Speaking of February 1920, Mr. Willis says: "its negligible rains belied once again its cognomen of Filldyke February; . . . according to my own station's records, Filldyke February is the driest month of the year". The matter cannot be so casually dismissed. The cognomen is "fill dyke", not "fill raingauge", and the distinction is an important one. The water seen in a dyke represents drainage from the land, and this is determined not only by the rainfall, but also by evaporation and the state of the soil. The latter factor depends on past rainfall as well as present rainfall. Under the conditions of rainfall and evaporation normally prevailing in Great Britain, the flow of streams and the level of underground water reach a maximum in late winter. There is, in fact, no month of the year to which the cognomen 'fill-dyke' could be more justly applied than to February.

The text is followed by a very interesting collection of photographs. It was a singularly happy idea of Mr. Willis's to photograph the same clump of snowdrops on January 1 every year, as an index of the state of vegetation—and a plant is a good indicator of integrated weather. The procedure was extended to other plant subjects and other dates, and several series of photographs are here reproduced. It is interesting to look at these pictures in conjunction with the table of monthly mean temperature on p. 106. They illustrate the effect of warmth during winter and early spring very forcibly and graphically.

The chronological form of presentation gives this book a very definite value. In times of peace a vast mass of meteorological information is published, but it is not always easy for an inquirer to find what he wants. What was the year of the great Christmas snowstorm? What was the date of the famous display of the aurora a few years ago? Questions of this sort can be answered more readily by reference to Mr. Willis's book and its index than by any other means known to the present reviewer. If for no other reason than this, it is well worth possessing.

E. G. BILHAM.

ARABLE FARMING ON POOR LAND

The Economics of Poor Land Arable Farming
Based on Surveys of Difficult Farming Areas in the East Midlands. By Dr. S. M. Makings. Pp. viii+280. (London: Edward Arnold & Co., 1944.) 18*s*. net.

EVERYONE must have been aware that all was not well with farming in the years between the Wars, but while the complaints of farmers were widely heard, there were few even in agricultural circles who had access to the full facts of the situation. The main problem is to be found among those who are committed to the poorer soils. With this in view, Dr. Makings has made a special study of the economics of certain poor land areas in the East Midland Province of England. In his work in the Economics Department at the Midland Agricultural College, he had access to the records and, so far as they existed, the accounts of a large number of farms in depressed areas. This material forms the basis of the book; it has been sifted and tabulated to give a clear picture of the business aspect of a cross-section of poor land arable farming, and the picture is none too bright. The conclusion is that under the conditions prevailing before the War, and in spite of a measure of government assistance, many farmers in these chosen areas, and particularly those handling the smaller units, were losing money.

The three districts chosen for the survey each suffered from certain definite soil, climatic or special limitations that made for low level of output, and greatly increased the risks that are inherent in production based on living things. In the Sherwood Forest area of Nottinghamshire, hungry, acid sand and the incidence of spring droughts put a heavy handicap on arable farming; in the poor Wolds of Lincolnshire, the thin poor soil and its exposed situation were the dominating factors; while in the Lincolnshire Carrs of the Ancholme Valley, it was lack of drainage rather than soil poverty that put its stamp on farming. The reader derives a clear picture of farming in each of these districts, partly from apt little summaries of the layout and balance of a number of typical farms, and in more precise terms from financial data derived from groups of farms. The Forest and the Wold both depended on the classical four-course rotation which, so long as sheep and barley prices were maintained, was probably the best system for these lands, but in recent years it has become clear that some fundamental change was necessary, and the author sets out the financial results of some of the alternatives that have been forced on the occupiers of these depressed areas.

The question is not entirely one of soil, although it is shown that farmers on better land can intensify and diversify their enterprises much better than their less fortunate neighbours. All the factors that enter the problem are discussed—land tenure, capitalization, and the technical qualifications of the occupiers. Finally, there is the national aspect of the farming of marginal land, not so much as it exists in war-time, but as it will appear after the War with even more land in this uncertain position than we had before. Two preliminary chapters set out the economic background to the detailed study, and a final chapter presents the main conclusions. The book is a thoughtful contribution to an important subject.

THE LAWS OF NATURE*

By PROF. HERBERT DINGLE
Imperial College of Science and Technology

Contrast in Character of Motion and Temperature Laws

IT would, however, be premature to conclude that because the laws of temperature in this one respect follow more closely the outlines of bare experience, they are therefore necessarily purer or more worthy of preservation than the laws of motion. We must look more closely into the matter, for it may be that, when the necessary supplementary clauses, so to speak, have been added, the type of law which has been constructed to describe motions is, by its greater scope, more adaptable to further experiences than the type constructed to describe temperature changes.

To examine this point we may usefully return to our examples of a ball thrown into the air and bodies at different temperatures placed near one another, to see how the difference of description, not inherent in the essential experiences, is introduced in the chosen terms of expression. The ball, it will be remembered, could, and in fact did, reverse its path, while the temperatures of the two bodies moved only towards equality. How did this come about ?

'Bare experience' would have required the ball only to fall, for its tendency is to move towards the earth. Hence something must have interfered with its natural behaviour, and, in fact, we did throw it up, thereby making it take a path it would not by itself have chosen. In order to describe its motion completely, therefore, we must state not only the law of motion but also the initial occurrence which set it moving. No importance is to be attached to the fact that this was a human interference with natural processes, for the same thing might have happened without human agency ; for example, the ball might have been thrown up by a volcano. The essential fact is that the motion cannot be described by the law of motion alone, but needs the statement of the law of motion plus a particular event. According to the character of this event the motion can be in one direction or in the opposite one, and the law of motion by itself must therefore be broad enough to allow both possibilities if it is to cover all the motions that occur in Nature.

The same thing is true, of course, on the larger scale. The planets might have revolved round the sun in the opposite direction so far as the laws of motion are concerned. To explain why they move in the direction observed we must know something of the origin of the solar system. When the circumstances in which they became detached from the sun are known, their motion is completely determined by the laws of motion, and no room is left for the possibility that they might have moved differently. The laws of motion thus establish their freedom by shifting the onus of distinguishing between opposite courses on to the shoulders of a 'boundary condition' ; and when we deal with something so vast and ancient as the universe, this boundary condition lies so far in the past that we are apt to forget that it is there. Consequently we think that the course of development of the universe has the same freedom as the untrammelled laws of motion. In that, however, we are wrong. So far from releasing us from difficulties concerning the origin of things, the laws of motion make it essential that we shall face those difficulties, for they are framed in such a way that otherwise their requirements are necessarily ambiguous.

Now so far as possibilities are concerned, temperature phenomena are in precisely the same boat as the phenomena of motion. In saying that the ball could move up or down whereas the two bodies could only tend towards equality of temperature, I was in fact making an incorrect statement, and if you did not notice it, that is only an indication of our extreme susceptibility to error through accepting laws of Nature as equivalent to bare experience. It is quite possible for the hot body to become hotter and the cold body colder if we choose our initial circumstances properly. For example, a gas expanding suddenly may cool and give its heat to another gas originally hotter. Such circumstances occur much less readily on the earth than do movements against gravity, and we are therefore liable to overlook their possibility. But in principle there is no difference at all in this respect between motion and temperature exchange, and there is no fundamental reason why laws of temperature should not have been constructed permitting a reversible exchange of temperature and requiring supplementary boundary conditions to determine what would happen in a particular case. If that had been done, there would have been no formal difference between the modes of treatment of the two phenomena, and I should have had to choose another subject for this lecture.

It has not been done, however. Perhaps owing in some measure to the fact that in everyday experience the temporary flow of heat against a temperature gradient generally needs the establishment of highly artificial conditions, while the temporary movement of bodies against gravitation is a very common occurrence, a different approach to the problem has been made ; and instead of describing a thermal phenomenon in terms of the rate of change of temperature with time, as we describe a kinematical phenomenon in terms of the rate of change of position with time, we describe it in terms of a new conception, *entropy*, which has no analogue in the present formulation of mechanical laws. The characteristic of entropy is that, no matter whether heat flows from the hot to the cold or from the cold to the hot body, the entropy at the end is always greater than the entropy at the beginning. (There is, it is true, a theoretical possibility that the entropy may remain unchanged, but in practice that can be ignored, and even theoretically it is impossible for the entropy to decrease.) This statement is true only if the *total* entropy is taken into account—the entropy of the hot and cold bodies and of any other body or system which has any influence at all on the process.

By this device we give direct and immediate expression to the one-way tendency of bare experience. We do not need first to give phenomena a round-trip ticket, and then to limit its validity to one direction only according to the ticket office at which it is presented. Whatever happens, whether bodies tread the natural path of temperature equalization or by violence are forced along the opposite course, the entropy of the whole system increases.

No such function as entropy, I have said, exists in the laws of motion, but there seems no fundamental reason why it should not be derivable. Every incidental motion in the universe contributes in its own measure to the grand one-way march of bare experi-

* Continued from p. 736.

ence, and should not be inherently incapable of representation in terms of an ever-increasing (or ever-decreasing, it does not matter which) function which for the purpose of reference we may call 'motion-entropy'. Motion-entropy would increase when an apple fell to the ground, and it would also increase when we threw our ball upwards—provided, of course, we took into account its change in ourselves and in the earth on which we pressed more heavily when we threw, as well as its change in the ball. If motion-entropy were formulated, we could destroy the formal difference between the laws of motion and those of temperature exchange in another way, by bringing the former into line with the latter, instead of by the reverse process.

On the face of it, this would seem the more desirable thing to do, for a direct expression of experience seems preferable to an indirect one. There is a penalty to pay, however. The conception of entropy is such that it has meaning only with reference to equilibrium conditions. Consider our two bodies again, and let us suppose that at the beginning their temperatures, though different, are steady. We can then evaluate their entropy—relative to an arbitrary zero, it is true, but that is of no importance here. Now let them interact with one another. After the lapse of a certain time their temperatures will have become equal, and then they will remain steady again. We can now again evaluate their entropy, and we find, according to the law, that it is greater than it was before. And that is all that the law can tell us. During the interval between the two steady states we cannot say that the entropy has steadily increased; we cannot, in fact, say anything at all about it, for the conditions essential to its significance do not exist. And since, in actuality, things are never in equilibrium, it follows that, in strict truth, we can never assign a precise entropy value to any actual system of bodies, let alone the whole universe. That is one reason why, as we saw, we could not apply our temperature laws to any system not enclosed within a boundary, for a boundary is necessary, though not sufficient, for equilibrium. Our assumption that our two bodies were originally at steady temperatures was an illegitimate one; there is no known process for keeping them so.

It should be understood that equilibrium here has a perfectly definite meaning, and is not subject to the arbitrariness arising from the possibility of changing our terms of expression. I mentioned earlier that a body at constant temperature could be regarded as an inert mass or as constantly interchanging energy with its surroundings, and that we could choose which form of expression we liked. That is true, but the laws of temperature I am speaking about now—in particular the law that entropy always increases—are framed after we have made our choice, and the choice is such that a state of constant temperature is a state of equilibrium so far as temperature is concerned, and a state of varying temperature is not a state of equilibrium. We cannot satisfy the condition for the significance of entropy by conceptually petrifying into equilibrium whatever state we may be confronted with.

The case again is not improved by the adoption of some physical picture of entropy, such as the very common and very convenient though very dangerous one which relates it to 'organization'. That representation was adopted after the discovery of the significance of entropy, and its validity is entirely dependent on its faithful conformity to the characteristics of entropy regarded as a simple mathematical function of certain thermal quantities. 'Organization' is a term of expression of a term of expression, and as such it has aspects which have no connexion with the facts of experience; it allows us, for example, to assign a precise measure of probability to occurrences which we have no reason to suppose are even possible. We can attach no weight to long-distance extrapolations of a process of disorganization which could not be reached also by extrapolations based on the original meaning of entropy, and we shall therefore not concern ourselves with them.

Strictly speaking, then, the entropy of an actual system can never be determined, but in practice we can often arrange to isolate a system sufficiently well for it to appear to be in equilibrium for a finite length of time, and we can then calculate its entropy. In such cases, in spite of its strict meaninglessness, the conception is extremely useful. We always find that the combined entropy of the system and its surroundings is increased when a change occurs, and our assumption that the entropy of the universe is continuously increasing is based on this fact. Such a conclusion, however, I must repeat, is rigorously a meaningless statement, and can only by courtesy be called an unprovable assumption.

The laws of motion do not suffer from this disability. They enable us to follow our ball throughout the whole duration of its flight, whether it is moving upwards or downwards, and make no demand that the system shall be in equilibrium. They have therefore much to compensate them for their excessive latitudinarianism, and make up by attention to detail what they lack in self-sufficiency.

The result of our analysis, then, is this. Our experience, both of the motions and of the temperature changes of bodies, shows that at present the processes going on in the universe tend in a certain direction and not in the opposite one. We describe this tendency for purposes of precise calculation by choosing terms of expression which form the alphabet of physical laws, and since time is included among these terms of expression, the laws allow us to extrapolate to the distant past and the distant future. The terms we choose for motion, however, differ in character from those which we choose for temperature, in that they lead to a different type of law. The former lead to reversible laws, which describe every detail of the changing process, but leave to an unknown 'original state' the task of determining why the process goes in one direction rather than the opposite one. The temperature laws, on the other hand, indicate the direction of the process without reference to an original state, but cannot be applied unless we can contrive or assume that the system in which we are interested is brought to a condition of equilibrium on two successive occasions: they then require that a certain quantity is greater on the second occasion than on the first, but can tell us nothing about the course from the first to the second condition of equilibrium.

Historical Aspect of the Laws of Temperature

Neither type of law affords grounds for dogmatizing about the distant past or future of the universe, and it is perhaps not altogether profitless to have achieved a realization of even that modest result. It is a matter of some interest to inquire why, when the bare experiences follow such similar lines, we should have chosen laws of such different types for describing them. I suggest the following explanation.

The earliest progress in science was naturally concerned with motion, for that is the phenomenon most easily examined with precise measuring instruments. Our theoretical scale of time measurement, for example, was chosen by assuming a body moving freely in space, and defining equal times as those in which it covered equal distances. A radiating body, such as the sun, might have been chosen instead of a moving body, and equal times defined as those in which it melted equal masses of ice, say, but the practical difficulties would have been greater. A kinematical measure was therefore chosen, *and then applied universally*—in particular, to the description of temperature phenomena when they came to be examined. Temperature thus, from the beginning, inherited terms of expression chosen originally for the analysis of motions instead of developing along its own intrinsic lines.

This procedure was further established by practical needs. We required to know how *work* (a concept belonging to mechanics, the science of motions) could be obtained from heat before we were very far advanced in the study of temperature phenomena themselves, and accordingly the additional terms of expression chosen for the laws of temperature were those found to be best adapted to the description of the transformation of heat into work, and not those best fitted for the study of heat for its own sake. The theoretical temperature scale, for example, was based on the amount of work obtainable from heat, and not on simple thermal effects alone. The result of this unnatural union between the representatives of motion and temperature was the birth of entropy, a quantity which was conceived in order to afford a measure of the availability of heat for transformation into work. Nothing parallel to this, of course, existed in the science of motion, and so no corresponding concept was created there.

It may be argued that this was a fortunate circumstance, and that the thermodynamic conceptions thus originated are more favourable for rapid and permanent progress than pure thermal conceptions would have been. From the point of view of the understanding, apart from the exploitation, of Nature, however, this seems to me very unlikely. Certainly our ultimate aim is to unite the sciences of mechanics and heat, but I think the soundest basis for a satisfactory union would lie in the existence of two strong independent sciences established on similar lines. We have brought about a union long before the science of heat has reached maturity, and so forced on it an unnatural development. The incompatibility between the motion and temperature laws is a result of this, and is not a happy augury for future connubial bliss. I venture to propose a return to first principles, and the creation of an independent science of heat, with concepts and laws of its own.

The obvious starting point is the phenomenon of radiation, for of all the modes of temperature exchange that occur, this is overwhelmingly the most important in the universe as a whole. It is indeed impossible to express how utterly insignificant all other temperature phenomena become when compared with it. To take a single example, the sun, a dwarf star, radiates some 4×10^{33} ergs of energy every second to space. On the other hand, the energy available, through all terrestrial processes—production of fuel, human and animal metabolism, etc.—for transformation into work does not exceed 5×10^{19} ergs per second, and if we suppose one tenth of this to be so converted, we see that the radiation from one dwarf star is about 10^{15}—a thousand million million—times the total terrestrial transformation of heat into work in the same time*. How many times the number of stars equivalent to the sun exceeds the number of planets on which work is artificially produced from heat we do not, of course, know; but, whatever it may be, when we consider that the terms of expression and laws of temperature phenomena have been shaped by this terrestrial 'gnat' and then foisted on the multillions of stellar 'camels' throughout the universe, we begin to realize something of the anomaly which has occurred.

Thermal Relativity

There is, however, another reason why we should —indeed, I would go further and say why we *must*— reform our present treatment of radiation. Progress in the study of motion has in the last generation brought to light a fundamental principle which, it is generally acknowledged, is valid throughout the whole of scientific inquiry, and this principle is violated in our present theory of radiation. I refer to the fundamental justification of the theory of relativity, namely, the principle that our theories should not imply the possibility of observing what is, in fact, inherently unobservable. It was this principle that destroyed the materialistic ether doctrine of the nineteenth century. Motion through the ether eluded observation so consistently as to force acknowledgment of the idea that it was inherently unobservable, whereupon the whole science of kinematics was reformed in such a way as to require that any experiment made to observe such motion must necessarily fail. The only observable motion is motion of one body with respect to another, and accordingly the word 'motion' now carries with it the quality of relativity, so that we cannot speak of it without implying the existence of some locatable frame of reference.

Now absolute radiation is unobservable in precisely the same way as is absolute motion, but while we have dismissed the latter from the terms of expression of motions, we still retain the former among the terms of expression of radiation phenomena. Consider two bodies relatively at rest. We used to say that each had an absolute velocity, v, and that they were relatively at rest because their absolute velocities were equal. We have now discarded the idea of absolute velocities, and associate no motion with the bodies. But consider two bodies at the same temperature. We used to say, and we still say, that each has an absolute temperature, θ, as a result of which it radiates a certain definite amount of energy, and that we do not observe any effects of the radiation because each receives from the other the same amount of energy that it radiates. But this absolute radiation, just like absolute velocity, is essentially unobservable. We should, then, in accordance with our principle, cease to employ it in our theories, and express the laws of radiation in such a form that it has no significance.

This, of course, means a radical reform of the laws of radiation, but I can see no escape from its necessity unless we deny the basic justification of the theory of relativity. When we reflect on the matter, we see other points of resemblance between the sciences of motion and radiation, which, indeed, is not surprising in view of the fundamental parallelism of the bare experiences already pointed out. For example, the

* I am indebted to Sir Alfred Egerton for the data concerning terrestrial processes.

development of the mechanical theory of relativity showed that gravitational and inertial mass, two quantities which, according to the former view, just happened always to be equal, were, in fact, essentially the same thing. In the theory of radiation we have likewise two quantities, radiative power and absorptive power, which similarly just happen always to be equal. We might expect that these two quantities, in a reformulation of the theory of radiation, would also be revealed as the same thing. Again, there is in temperature, as in motion, a limit approachable only asymptotically by material bodies ; we call one the absolute zero of temperature and the other the velocity of light. The fact that in temperature there is only a lower limit, whereas the velocity of light is a limiting velocity for motion in all directions, is merely a characteristic of our method of measurement. We have already seen that a measurement of velocity in terms of the Doppler effect would have given us a finite limit in one direction and an infinite one in the other, and we could equally well choose a scheme of temperature measurement (Kelvin, in fact, at one time proposed such a scheme for his 'absolute' scale) which would place the 'absolute zero' at 'minus infinity'.

I have attempted[4] a re-expression of the phenomena of radiation, along the lines of the relativity treatment of the phenomena of motion, in which temperature is measured in terms of the rate of change with time of some observable characteristic of the radiating body, just as velocity is measured in terms of the rate of change with time of the spatial position of the moving body. The 'observable characteristic' could be the energy radiated by the body, expressed in terms of the readings of a suitably defined instrument, but I have found it more convenient to choose an instrument which records something analogous to the entropy change of the body ; I will denote it by the Greek letter η. That, however, is a detail ; the important thing for our present purpose is that temperature is measured in terms of a temporal process instead of by the reading of a thermometer in equilibrium, and the measurement of time involved is made by a thermal clock instead of a mechanical clock.

To understand the character of a thermal clock, let us look for a moment at the character of a mechanical clock. Here some specified body moves over a dial on which equal spaces are marked out, and equal times are those in which equal numbers of spaces are covered by the moving body. The fundamental clock is that in which the 'specified body' is a beam of light (this, of course, is only another way of expressing the familiar 'postulate of the constancy of the velocity of light' familiar to students of the theory of relativity), and clocks for practical purposes are constructed so as to give the same scale more conveniently. The time-scale suitable for the description of motion is thus one in which equal times are defined in terms of equal spaces, conformably with the measurement of motion by velocity defined as the rate of change of space with time. Similarly, the time-scale suitable for the description of radiation is one in which equal times are defined in terms of equal amounts of η, conformably with the measurement of radiation by temperature defined as the rate of change of η with time. Instead of the strictly specified body (a 'hand') moving over a space-scale (a 'dial'), we have a strictly specified body radiating to an η-measuring instrument, and equal times are those in which equal quantities of η are recorded by the instrument. We have to wind up the mechanical clock to keep its specified body moving continuously, and similarly we have, of course, to supply heat to keep the specified radiating body radiating continuously. In other respects also the two procedures are perfectly analogous.

In this way we provide a set of concepts, or terms of expression, for the description of radiation, which are intrinsic to the subject itself and not imported into it from without. The result is that just as mechanics has turned to advantage its choice of time measurement in terms of space by forming a unified conception of space-time, so the study of radiation along the lines suggested can turn to advantage its choice of time measurement in terms of η by forming a unified conception of η-time. To see the analogy, let us recall that in the ordinary theory of relativity the 'interval' between two events in the history of a moving particle is made up by combining a space increment with a time increment, and the relative magnitudes of these two components vary with the velocity of the co-ordinate system—that is, the velocity of the measuring instruments. When the co-ordinate system moves with the body, the interval consists entirely of the time increment, but for other velocities it is partly a time increment and partly a space increment. A similar thing is true of radiation. If we examine the radiation of a body with an η-measuring instrument and a thermal clock at the same temperature as the body, the former instrument records nothing and the thermal interval is wholly thermal time ; but if we use instruments at a temperature different from that of the radiating body, they both give finite records, and the transformation equations connecting the readings at one temperature with those at another (the thermal 'Lorentz equations') are such that a total thermal interval exists which is the same for all temperatures of the instruments.

The concept of η-time thus arrived at can be given a geometrical interpretation corresponding to that given to space-time by Minkowski. The null geodesic in space-time corresponds to motion with a velocity of $\pm c$, and that for η-time corresponds to radiation at a temperature of the absolute zero or infinity. There is the difference, however, that whereas space-time is 4-dimensional since space has three dimensions, η-time is 2-dimensional ; but, on the other hand, while the co-ordinate expression for the space-time interval is quadratic, that for the η-time interval is quartic. The geometries applicable to the two cases are thus different, and I have so far not been able to proceed beyond what I may call the 'special' theory, in which only constant temperatures are considered, just as in the special theory of mechanical relativity only constant velocities are considered. Constant velocities are appropriate to motions in a world of zero masses, and, similarly, constant temperatures are appropriate to radiation by bodies of infinite heat capacity. There is throughout a close parallelism between the new thermal and the current mechanical terms of expression, and we have an earnest of the possibility of ultimate amalgamation into a much more natural thermodynamics than the existing science of that name in the fact that thermal and mechanical time, though quite differently defined, give identical scales, and at any fixed temperature and velocity could be given the same unit. This is a necessary consequence, of course, of the experimental fact that a body at constant temperature radiates at a uniform rate according to our ordinary mechanical clocks.

The special theory of thermal relativity describes the same facts of experience as the current theory of radiation, but uses fundamentally different concepts for the purpose. So far as I can see, it entails nothing new in the field of observation, and in this respect it differs from the special theory of mechanical relativity which, when it superseded the earlier ideas based on absolute space and time, led to such discoveries as the dependence of mass on velocity, the equivalence of mass and energy, and other important relations. There are, however, two reasons for this. In the first place, pre-relativity mechanics was almost entirely concerned with velocities far from that of light, and the new requirements of the relativity theory thus related to conditions of which no experience had been obtained. The current absolute theory of radiation, however, is based on a relatively much wider range of experience, including that of phenomena at temperatures approaching the absolute zero. It has accordingly already adapted itself to the regions where anomalous results would be expected, so that the new theory is robbed of its chance of springing a surprise. Secondly, the general field of validity of the special theory of mechanical relativity —namely, the region of phenomena which can be discussed without considering the accelerating effects of gravitation—is a very large one, giving scope for many applications of the new principles. The special theory of thermal relativity, however, has scarcely any scope, for in all ordinary phenomena the effect of radiation is to lower the temperature of the radiating body very rapidly, and so to give variations of the radiation, the neglect of which is out of the question. Only bodies of very large heat capacity, like stars, come within its power, and we cannot make experiments with stars. New discoveries would therefore be expected to await the formulation of the general theory. But for our present purpose that is of little moment, for we are concerned more with the character and terms of expression of the laws than with the facts they represent, and these are as well exhibited in the special as in the general theory.

Whatever, then, may be the value of a thermal relativity theory from the heuristic point of view, it does, I think, show conclusively that it is possible to express the facts of radiation in terms totally different from the traditional ones, and so to preserve in our laws of motion and temperature the similarity of character inherent in the bare experiences. Each set of phenomena employs only concepts peculiar to itself—in mechanics, space and 'mechanical' time, and in temperature, η and 'thermal' time—and the measurements of the associated quantities are carried out by independent instruments. The connecting link is time, which, whether measured by the space covered by a moving body or by the η received from a radiating body, gives the same scale in the ideal cases of 'constant' velocity and 'constant' temperature. We can thus confirm the location of the rift in current physical theory in the arbitrary terms of expression chosen for our laws, leaving bare experience, if not necessarily quite homogeneous, at least sufficiently so to encourage the hope that a single scheme of law for all phenomena is a possible objective.

The One-Way Evolution of the Universe

Let us, in conclusion, look at the problem of the infinitely distant past and future from the point of view we have reached. We can say, first of all, that in so far as the problem arises from an extrapolation of existing laws, it is not a fundamental one. We can change the laws without violating experience. If they lead us into difficulties it may be necessary to do so, and if they lead us into contradictions or impossible situations we *must* do so. The fundamental difficulties are those which result from the trend of bare experience itself. If that leads us to an impossible situation, we must either fall back on the almost desperate expedient of trying to correlate our experiences without arranging them in a time order at all, or else capitulate and say that the universe is essentially irrational or (perhaps the same thing) beyond comprehension by human reason. I do not think, however, that we are yet reduced to that extremity.

In both its motion and temperature aspects the universe at present appears to be taking a one-way course. Its motions show a process of local consolidation and large-scale diffusion. This offers no problem for the future, for the diffusion can continue indefinitely and the consolidation tend asymptotically towards an eternally steady state. Working backwards to the past, however, we come by way of a large-scale consolidation and local diffusion to the idea of a single homogeneous mass, and, according to our present time-scale, this state would be located at a not infinitely remote epoch. The present discrepancy between the dates of this epoch yielded by the local and large-scale processes is a characteristic of our theories which can be ignored in our present considerations. What happened before this ? There is nothing that I can see to prevent that state having been reached by a gradual condensation of an originally infinitely diffused mass the rate of contraction of which, infinitely slow at first, accelerated until it culminated in a state of maximum density. After this a large-scale expansion could have proceeded, begun either by a rebound of a continuous mass from a state of compression, or by separate bodies simply continuing on their one-way journey after having made their closest approach to one another. Such a course of cosmic history would involve no problem of the distant past or distant future so far as motions are concerned.

What about temperatures ? The present trend is somewhat ambiguous. Our experience is so brief that we can detect no change in the temperatures of the stars, and any theories we may have on the matter are based on laws which we are now leaving out of account. Certainly there is a tendency towards equalization of temperature, shown by the fact of radiation from hot to cold bodies, but the probability is, nevertheless, that as we go backwards to remote times, the hottest bodies, the stars, become colder rather than hotter. I think it is in accord with present indications, so far as we can read them, to say that when we reach the time of maximum density of the universe, the stars, if they then existed, were cooler than now, and the temperature of the whole universe was more homogeneous. The tendency to local consolidation since that time has raised temperatures locally, and the large-scale expansion has checked the process of equalization. As we recede further into the past we contemplate a homogeneous mass of matter falling gradually in temperature step by step with its decrease in density, and there is no greater difficulty here than there is with the succession of motions. In the reverse direction, as we go from the present time towards the future, we presumably find the stars getting hotter up to a maximum temperature and then cooling, while all the time the

tendency towards equalization of temperatures by radiation goes on inexorably until ultimately the universe approaches asymptotically a state of uniform temperature.

We may sum up this picture of cosmic history, then, as follows. In the infinitely distant past the universe consisted of an infinitely diffuse, homogeneous mass at uniform temperature. With the passage of time the mass became denser and hotter until a state of maximum density was reached, and perhaps about this time the mass broke up into units. Thereafter a process of expansion went on, with the units getting hotter at varying rates but tending by radiation to come to a state of common temperature again. Ultimately they will reach and pass a maximum temperature, tending finally to a universe consisting of a number of aggregations of units at a common temperature performing eternally unchanging motions.

It should not be necessary to say that this is not intended to be in the slightest degree a theory of cosmogony. My purpose has been simply to give a conceivable course of development not inconsistent with the present trend of our experience, and involving no contradictions or insuperable difficulties in the distant past or the distant future. There may be a thousand such possible courses, and I am not concerned with the task of choosing between them. What I have tried to show is that not only does our present dilemma concerning the origin of things arise from our arbitrary laws, but also no such dilemma exists in the requirements of experience itself. The practice of 'induction of principles from phenomena', the origination of which Halley saw and did so much to facilitate, is still an endeavour worthy of our utmost effort.

[4] In course of publication.

TRANSFORMATION OF PNEUMOCOCCAL TYPES

By DR. W. T. J. MORGAN

Lister Institute of Preventive Medicine, London

GRIFFITH[1] was the first to show that an attenuated and non-encapsulated 'rough' (*R*) variant of one specific type of Pneumococcus could be transformed into a virulent and encapsulated 'smooth' (*S*) form of another specific type. The transformation was accomplished *in vivo* by injecting subcutaneously a small amount of living *R* culture of Pneumococcus Type II together with a relatively large inoculum of heat-killed organisms derived from a fully virulent *S* strain of Pneumococcus Type I or III. The living *R* strain alone failed to kill mice, whereas the addition of the heat-killed Type I or III organism caused a fatal bacteriæmia. The organism isolated from the heart's blood of the infected animals, however, was not a virulent Type II organism, but a virulent encapsulated Type I or III pneumococcus according to the type of the heat-killed *S* vaccine employed. The importance of this observation was soon recognized, and Griffith's findings were confirmed by Neufeld and Levinthal[2], Baurhenn[3] and Dawson[4]. Some time later, Dawson and Sia[5] succeeded in carrying out the transformation of *R* Type II pneumococci into a virulent *S* Type III organism by an *in tivro* procedure.

In order to bring about this change, it is essential that the *R* variant should be in a reactive phase, since it is only when in this condition that an *R* culture is found to respond to the transforming stimulus. Once the organisms have assumed the type-specific *S* characters, they remain true to form through serial transfers in ordinary media and through repeated animal passage. In this work the greatest care was taken that the *S* vaccines employed contained no viable organisms.

The earlier work of Dawson and Avery[6] and Dawson[4] showed that the conversion of *R* pneumococci to the *S* form of the same type could frequently be accomplished by growing the organism in anti-*R* serum. In effecting this transformation of type *in vitro*, anti-*R* serum is generally added to the culture medium, although it is recorded that the transformation can frequently be achieved in the absence of *R* antibodies. It is now known that to obtain repeatable results, sulphonamide inhibitors must be removed from the nutrient broth used as culture medium. The transformation has never been observed to occur in the absence of serum, and failure to induce the conversion of resting cells seems to indicate that transformation takes place only during the active reproduction of the cells. Attempts to use solutions of the *S* organisms, obtained by freezing and thawing and afterwards heating at 60°, in place of whole bacteria, were mostly without success. Alloway[7], using extracts of virulent Types I and III pneumococci, was successful in effecting the transformation of an *R* Type II culture into fully virulent Type I and III organisms respectively. The conversion of *R* Type II into *S* Type I was more difficult and usually required several sub-cultures before the conversion was finally established. Alloway showed that serum from the sheep, rabbit, guinea pig, horse or man could be employed irrespective of its content of anti-*R* immune-body, thus indicating that some property in serum other than the anti-*R* component is essential if transformation of type is to occur. The presence of the specific polysaccharide of a heterologous type failed to induce the conversion of *R* Type II organisms into the heterologous *S* form.

The transformation of *R* pneumococci into a virulent *S* form means that the organism has acquired the property of producing the specific capsular substance, which for the Type III pneumococcus has been shown to be a polysaccharide built up from 4-β-glucuronosidoglucose units[8]. It would appear, therefore, that in the presence of a specific factor contained in an extract of the *S* Type III organism, the *R* Type II pneumococcus develops the capacity to elaborate the Type III specific material. In a later paper, Alloway[7] showed that potent extracts, as active as the original *S* vaccine in causing the $R \rightarrow S$ transformation, were obtained by dissolving the *S* cells in sodium desoxycholate, and that the active factor could be freed from certain of the accompanying impurities by precipitation with alcohol, or by adsorption of the contaminating substances on charcoal.

After a lapse of rather more than ten years, progress on this subject has once again been brought to notice by the publication of a paper by Avery, MacLeod and McCarty[9] which describes the isolation and identification of the active transforming principle present in an extract of *S* pneumococci (Type III). The evidence of its nature is based on an examination by chemical, enzymatic and serological analysis, and by electrophoresis, ultracentrifugation and ultraviolet spectroscopy. Within the limits of the methods

employed, the active factor is shown to contain no protein, unbound lipid or serologically active polysaccharide. The material contains 34–35 per cent C, 3·7–3·8 per cent H, 14–15 per cent N and 8·5–9·0 per cent P, and these figures are in close agreement with those calculated on the basis of the theoretical structure of sodium desoxyribonucleate (tetranucleotide). It is probably no mere coincidence that it is this type of nucleic acid which is found as a constituent of nuclei and chromosomes and, as shown by Signer, Caspersson and Hammersten[10] and by Astbury and Bell[11], is the form of nucleic acid that can exist in a highly polymerized and reactive state.

Bacteria that give a positive Feulgen reaction[12], that is, bacteria that have the property of restoring the colour of a fuchsine solution decolorized by sulphurous acid, are generally considered to contain a nucleic acid of the desoxyribose type. Thompson and Dubos[13] found that after the removal of ribonucleic acid from pneumococci, the resulting Gram-negative organisms give a strong colour reaction with Feulgen's reagent. These workers were, however, unable to isolate desoxyribonucleic acid from pneumococci, whereas Schaffer, Folkoff and Bayne-Jones[14] working with *Escherichia coli* and Johnson and Brown[15] with tubercle bacilli obtained nucleic acids from these organisms that appeared to be essentially of the desoxyribose type. Avery, MacLeod and McCarty are the first workers to isolate a desoxyribonucleic acid from Type III pneumococci and to accomplish an *in vitro* transformation of *R* Type II pneumococci into the *S* form of the heterologous Type III organism by means of this substance.

It is of considerable significance that an *R* bacterial cell in the presence of a desoxyribonucleic acid is stimulated to produce the specific capsular polysaccharide characteristic of the heterologous pneumococcus from which the nucleic acid molecule was itself derived. Although the transformation described by these workers is limited to a single type of change, it seems probable from the observations of earlier investigators that the process is one of general application. If a similar type of substance derived from other *S* cultures is found to bring about *in vitro* transformations of this kind, then it will appear probable that the desoxyribonucleic acids possess different biological specificities, as distinct from serological specificity, and that these can be recognized according to the nature and specific character of the capsular polysaccharide formed. Up to the present, little is known concerning the immunological specificity of the nucleic acids. Recently, Lackman, Mudd, Sevag, Smolens and Wiener[16] have shown that both *d*-ribo- and *d*-2-desoxyribo-types of nucleic acid react irregularly and with considerable serological overlapping when examined with anti-pneumococcal serum. The specific reactivity of certain anti-pneumococcal sera for nucleic acids can be specifically inhibited not only by the purines present in the nucleic acid but also by the methyl-purines, caffeine and theophyllin. Precipitins of similar reactivity do not occur in normal sera, so that it would appear that the anti-nucleic acid component of the serum has been formed during immunization with the pneumococci. It may be, however, that significant changes are induced[17] in the highly polymerized and complex nucleic acid molecules during the isolation and purification procedures generally employed, and that little progress will be made in establishing a relationship between chemical constitution and immunological specificity in this group of substances until they can be recovered in the native condition from tissues and bacterial cells.

It appears probable from the work of Avery and his co-workers that there exists within all types of pneumococci an enzyme which passes into solution during autolysis and rapidly destroys the activity of the transforming agent. To obtain optimal conditions for the conversion it is essential, therefore, to employ young cultures during the logarithmic phase of growth, since under these conditions cell division is most active and autolysis minimal. Although there is as yet no definite evidence as to the exact nature of the biochemical processes that operate during the transformation, it seems certain that a co-ordinated series of enzymatic reactions results which finally leads to the formation of the specific capsular polysaccharide and of the transforming agent itself. Once initiated, the process of forming these newly acquired characters continues through innumerable transfers of the organism without the addition of further transforming agent. Avery, MacLeod and McCarty point out that the experimentally induced alterations are definitely correlated with the development of a new morphological structure—the capsular polysaccharide—and the consequent acquisition of new antigenic and invasive properties. The changes are predictable, type-specific and heritable, and indeed the inducing substance has already been considered to be gene-like and the capsular substance to be a gene product. If one assumes that the desoxyribonucleic acid and the transforming agent are one and the same substance—as the experimental evidence strongly indicates—then the transformation of *R* Type II pneumococci into *S* Type III pneumococci represents a change which is chemically induced and specifically directed by a known chemical substance.

The genetic implications of this work are considerable, for it would appear that the transformation is a gene mutation and that the $R \rightarrow S$ change induced is, in fact, an authentic example of the accomplishment of a controlled mutation by a specific chemical agent. Examples of similar changes with other biological material, such as the conversion of the virus of rabbit fibroma (Shope) into that of infectious myxoma (Sanarelli) by Berry and Dedrick[18] and Berry[19] have already been given, and many more will certainly be forthcoming. This type of research is fundamental in character and of outstanding importance.

INVASION OF THE NEW WORLD BY *ANOPHELES GAMBIÆ*

By DR. JOHN SMART
British Museum (Natural History)

"ANOPHELES GAMBIÆ in Brazil" is the title of a recent book[1] by Fred L. Soper and D. Bruce Wilson, in which is related the story of the recent incursion, and defeat, of the African mosquito, *Anopheles gambiæ* Giles, into South America. The importance of this book is that it is the record of man's first whole-hearted deliberate attempt completely to eliminate a small insect vector of disease from a geographically large area.

Previous campaigns against insects have usually attempted the elimination of the species from an area of limited size, or the aim has been merely to 'control' the species. 'Control' implies keeping the population of the species down to a level at which the depredations of crop pests cease to be economically important, epidemics due to insect-borne disease cease, a pandemic is driven back into small endemic centres, or the incidence of the disease reduced to a figure that is considered satisfactory. Striking examples are the control of the coco-nut beetle (*Promecotheca reichei* Baly) in Fiji[2], the extermination of the Mediterranean fruit fly (*Ceratitis capitata* Wiedemann) in Florida, where it had gained a foothold[3], and the elimination of urban yellow fever in South American cities by the local eradication of the tiger mosquito (*Aedes* (*Stegomyia*) *ægypti* Linnæus)[4]. 'Control' has one great disadvantage over complete eradication of a species in that the control measures have to be continuous.

Anopheles gambiæ was a purely Old World mosquito widespread in the Ethiopian region. However, in March 1930, R. C. Shannon collected it at Natal, Rio Grande do Norte, Brazil[5]. It is thought that the fast surface-mail service established by the French between Dakar and Natal rather than aeroplanes was responsible for its introduction, since there had been only three Africa to Natal aeroplane arrivals before Shannon's discovery. The late Dr. Adolf Lutz, veteran entomologist of the Instituto Oswaldo Cruz, had surveyed the area around Natal in 1928 in connexion with proposed sites for a leper colony, and he had pointed out to the authorities the danger of mosquito importation from Africa consequent on the development of rapid trans-Atlantic transport[1,6].

Ecologically, the district around Natal was not particularly favourable to *A. gambiæ*, and, with luck, the mosquito might have failed to establish itself: the problem created by its arrival looked like being one of localized control, until the mosquito just died out. This being so, the Yellow Fever Service (a joint organization of the Brazilian Government and the International Health Division of the Rockefeller Foundation) undertook immediate measures against *A. gambiæ* around Natal. This optimistic attitude was, however, shattered when, in April 1931, severe epidemic malaria broke out in the surrounding districts. Malaria had been endemic in some of these districts, but the new epidemics were so bad that wholesale emigrations of the populace were taking place. These epidemics were due to the presence of *A. gambiæ*, acting as a vector; a year after being first discovered on South American soil, the mosquito had spread a distance of 182 km. from its first recorded foothold.

The locality of the initial infestation by *A. gambiæ* was a district where tidal flats had been transformed into 'freshwater hayfields' by the erection of dykes to exclude the tidal salt waters. *A. gambiæ* could have been eliminated at this stage by opening the dykes and admitting the salt water. This action was, in fact, recommended in May and September 1930, and again later, but it was only after the disastrous malaria epidemic of 1938 that it was done, the local health officers not having sufficient powers to overcome the opposition of the interests which stood to suffer loss by the opening of the dykes.

The localized work of the Yellow Fever Service cleaned up the situation around Natal, and the danger to the State capital having been removed the local authorities became disinterested in the matter though, fortunately, the workers of the Rockefeller Foundation continued to keep an eye on *A. gambiæ* in the outlying districts.

During 1932–37 *A. gambiæ* spread slowly, but little attention was paid to it until, in 1937, the mosquito was suspected of being responsible for localized epidemics of malaria, and in 1938 it was proved responsible for severe outbreaks of epidemic malaria in the coastal regions of Rio Grande do Norte, north of Natal and in the valley of the Jaguaribe River in the neighbouring State of Ceara. This epidemic wrought such havoc that tax-holidays had to be declared in certain localities and travelling representatives of business houses refused to enter the affected districts.

The State Governments appealed to the Federal Government, and in August 1938 the President of Brazil signed a decree creating the Anti-Malaria Service. This service was immediately organized under Dr. Manœl Ferreira, and a laboratory for research on *A. gambiæ*, as the species occurred in Brazil, was set up at Natal under Dr. Cesar Pinto of the Instituto Oswaldo Cruz[6]. The International Health Division of the Rockefeller Foundation, already actively co-operating with the Federal Government in the highly successful Yellow Fever Service, continued to keep an eye on the situation. In the course of preliminary discussions with the Brazilian Government it was concluded that if the spread of *A. gambiæ* was not stopped a major disaster threatened the Brazils, and no one could tell how many of the Americas would eventually be affected. It was therefore agreed that any programme of work should aim at the immediate eradication of the species.

In January 1939 arrangements were completed for collaboration between the Anti-Malaria Service of the Brazilian Government and the International Health Division of the Rockefeller Foundation in a new organization to be called the Malaria Service of the Northeast. This new body immediately set going a medical treatment campaign, commenced the systematic disinsectization of all vehicles, boats and aeroplanes proceeding from the infested region to clear areas, and made an immediate start on the actual attack on the mosquitoes themselves. At the peak of its activity the personnel employed exceeded 3,500, but the maximum number of medical men employed was forty-nine. During the period of its existence the Service used more than 6½ million tablets of atebrine and quinine. Some 11 million samples of water were examined for mosquito larvæ; more than 104 million collections of water were treated with anti-larval measures, 261,292 kgm. of Paris-green being used for this purpose; 720,906 litres of insecticide were used to disinfest houses,

vehicles, etc., of the adult mosquitoes. In 1940 alone 7,036,731 mosquito larvæ, of which 17,425 were *A. gambiæ*, and 972,248 adult mosquitoes, of which 56,780 were *A. gambiæ* were examined. The expenditure for for the whole period of the existence of the Malaria Service of the Northeast totalled 2,139,570.27 dollars.

The work of the first six months was not over-encouraging, but in the second six months localized eradications had been effected and the problem seemed to be resolving itself into one of administration. Early in April 1940, the vital experiment of stopping all control measures in an area that had previously harboured *A. gambiæ*, but which appeared to have been cleared of the mosquitoes, was made. *Anopheles gambiæ* did not reappear. The actual technique of destruction had proved simpler and more rapid than was at first anticipated, and faith in the ideal of complete and total eradication of the species began to grow by leaps and bounds. From this time anti-*gambiæ* work was stopped in any previously infested area after it had been found to be free from the mosquito for three months.

The clearance of areas allowed additional personnel to be concentrated on the less tractable districts, and this act was reflected in the rapidity with which the final stages of the elimination of *A. gambiæ* were accomplished. Less than two years from its inception, on November 14, 1940, the Malaria Service of the Northeast recorded the last evidence of infestation by *A. gambiæ* in Brazil, and in January 1941 all anti-*gambiæ* measures were suspended.

The evidence that *Anopheles gambiæ* has been eradicated from Brazil is all of a negative character, but Soper and Wilson[1] consider that it has, in fact, been effected. That reinfestation is possible has been shown by the recording by Soper and Wilson[1] of specimens of *A. gambiæ* found in aeroplanes arriving at Natal from Africa. In the future, vigilant disinsectization of aeroplanes must be insisted on.

The collaborative Malaria Service of the Northeast was brought to an end in the middle of 1942, having demonstrated that the goal of species eradication from a large area was attainable. Soper and Wilson[1] admit that there are features of the ecology of *A. gambiæ* which, related to the nature of the terrain invaded, favoured eradication. They also point out, however, that when species eradication is the goal aimed at, matters are simplified, compared with the institution of mere control measures, since the problem becomes a purely entomological one completely divorced from all medical and epidemiological considerations. The test of success is not the reduction of any selected index relating to the disease to some predetermined, or hoped-for, figure, but simply the complete and continued absence of the species attacked after the campaign has ended. The Malaria Service of the Northeast was fortunate in having available for incorporation the trained personnel of the Yellow Fever Service.

No amount of argument will prove that species eradication, as a method of dealing with malaria and other insect- or arthropod-borne diseases, is not applicable elsewhere. Only the failure of properly organized and adequately financed attempts will do so. The cost may be high, but against this must be set the ever-recurrent losses due to the diseases and the annual cost of such control measures as are in vogue. These measures may cost enormous sums of money in the long run, but it is notorious that men, when organized as a society, tend to prefer annual recurrent small expenditures even though they may be far less effective and be far larger in the aggregate than the cost of a short intensive campaign promising finality. Soper and Wilson[1,4] do not claim that the method of species eradication is applicable everywhere or to any vector. They point out that in the first place the presence of the vector must be creating a public health problem sufficiently grave to justify the expenditure of time and money involved and the interference with the life and rights of the community necessary for the efficient application of the anti-vector measures. Secondly, the vector must be one which can be attacked successfully; that is, it must be possible to seek out and discover the vector with comparative ease, and methods of killing it in its breeding places must be available. Thirdly, it must be possible to clean up an isolated area unlikely to be reinfested, or the area to be cleared of the vector must be sufficiently large so that the peripheral region, where measures will have to be persisted in to prevent reinfestation, will be small in comparison with the area cleared.

Soper and Wilson[1], discussing the problem of *A. gambiæ* in Africa, point out that there the eradication would have to be centrifugal, while the campaign in Brazil was a centripetal one; they also point out that the problem in Africa would be complicated by the presence of *Anopheles funestus* Giles, a very efficient malaria vector, alongside of *A. gambiæ*. They point to the isolated malaria-ridden valleys of Peru, where a single species, *Anopheles pseudopunctipennis* Theobald, is the vector[7], and the islands of the Caribbean, as localities where species eradication would seem particularly feasible.

Soper and Wilson[1,4] have stressed the desirability of tackling any case of species eradication as an immediate problem without any postponement of the attack on the species pending the completion of some elaborate programme of detailed research on that species. It is, however, perhaps pertinent to point out that a considerable amount of basic research had been carried out on *A. gambiæ* in its Old World home before it reached Brazil; the results of these researches were, of course, available to those responsible for the campaign against the species in Brazil. There is probably a judicious mean between the two policies, though individuals may tend to lean toward one or the other extreme.

It might be well worth while to consider the place that species eradication campaigns might have in relation to the Colonial improvement programmes that are being mooted at the present time. The personnel problem should not prove intractable, since it is likely that, on the cessation of hostilities, many members of the Forces who have been engaged on anti-malarial or other related entomological work will be returning to civil life and might welcome an opportunity to continue such work. Such personnel might well be used to form the core of species-eradication organizations, and staff for routine operations could be recruited from the local populations.

NEWS and VIEWS

Agricultural Research Council: Secretaryship

IT is announced that Mr. J. C. F. Fryer, director of the Plant Pathological Laboratory of the Ministry of Agriculture at Harpenden, has been appointed to succeed the late Prof. W. W. C. Topley as secretary of the Agricultural Research Council. Mr. Fryer is well known in scientific and official circles and his appointment to this responsible position is amply justified by his special qualifications. He has held his present post for a number of years and at one time it was combined with that of entomologist to the Ministry of Agriculture. Much of the improved technique applied in recent years to pest control has been the result of work initiated or fostered by Mr. Fryer in his official capacity. Educated at Cambridge, and for some time fellow of Gonville and Caius College, Mr. Fryer became Balfour student of the University. During his tenure of this studentship he carried out important researches on the genetics of butterflies in Ceylon and also investigated the fauna and physiography of Aldabra Island in the Indian Ocean. His subsequent career began with the Board of Agriculture and coming from a family well versed in farming experience he brought to his duties practical experience backed by scientific knowledge. His long and close association with this branch of Government service has left him comparatively little opportunity for other activities. Nevertheless, his name is among those who have occupied the presidential chairs of the Royal Entomological Society and of the Association of Applied Biologists. In the appointment of Mr. J. C. F. Fryer, the Agricultural Research Council has placed its secretaryship in exceptionally capable hands.

Stereoscopic Projection

ON June 17, at the Aldis Works, Birmingham, Mr. A. C. W. Aldis gave a demonstration of the stereoscopic projection. He employed special high-intensity projectors of his own design which gave a vivid impression of stereoscopic relief when viewed through the usual coloured anaglyphs. These projectors gave a remarkable efficiency with brilliant screen illumination in spite of the loss of brightness involved by the use of anaglyphs and coloured filters for the screen projections.

Mr. Aldis's approach was through the theory of stereoscopic vision. He invited his audience by suitable screen tests to determine their own stereoscopic appreciation, and produced by means of plane geometrical patterns projected from 50 ft. or more an impression, when viewed through anaglyphs, of a suspended luminous sphere which appeared to move towards the observer, meanwhile diminishing in size. The latter part of the demonstration showed the modern method of prospecting for minerals in jungle territory by means of stereoscopic photographs of the terrain, and was followed by scenes from the actual bomb damage in Germany including the Möhne Dam before and after the attack, the Eder Dam, the Herdicke Bridge and the damage to Mainz, Rostock, Düsseldorf and the Phillips Radio Factory at Eindhoven. These photographs, when viewed by stereoscopic vision, were particularly convincing, and the wealth of detail exhibited gave adequate testimony to the value of the method of projection which Messrs. Aldis have devised.

Penicillin Treatment of War Wounds

THE Medical Research Council's War Memorandum No. 12, entitled "The Use of Penicillin in Treating War Wounds" (H.M. Stationery Office, 1944. *3d.* net), is a valuable publication embodying the instructions issued by the Penicillin Trials Committee of the Medical Research Council. There is a prospect, says the memorandum, that large quantities of penicillin may shortly be available and in particular it may be possible to treat a considerable number of casualties in forthcoming military operations. The memorandum is intended to be a guide for the treatment of battle casualties and for the laboratory control of such treatment, and it does not pretend to be a guide to all the clinical uses of penicillin (for a note on these see NATURE, April 29, p. 521; 1944). Further, its instructions are provisional, because experience of the treatment of wounds with penicillin is still relatively small. The properties of penicillin are briefly discussed, and a list is given of the bacteria which are susceptible and resistant to it. Other sections deal with the preparation of penicillin and with its local and systemic administration, with its uses for particular types of wounds, with failures of the treatment and with the laboratory procedures which are necessary for the control of the treatment (diagnosis of the bacteria present, titration of the penicillin content of the blood and of the potency of the penicillin). The memorandum concludes with a valuable list of selected publications and memoranda on penicillin.

Polish Medical Science

THE medical issue of "Polish Science and Learning" (London: Oxford University Press, 1944. *2s. 6d.*), which is one of a series of booklets edited by the Association of Polish University Professors and Lecturers in Great Britain, is, its editors state, an attempt to lay a foundation for the future in collaboration with the scientific workers of other nations. The creation of the Polish Medical School and of the Paderewski Hospital in Edinburgh is, as Prof. Jurasz says in his article about them, a symbolic act, a practical demonstration of the determination of the Polish people to continue their national life in spite of all the sufferings of their country; and it demonstrates the existence of practical collaboration between two very different nations. It is perhaps difficult for some Englishmen to realize what hope and encouragement the creation of these two medical centres has meant to the Polish people. Already fifty-three students have graduated from the Polish Medical School. Many civilian students who are unfit for the Polish armed forces have joined it after leaving their schools in Great Britain, and others have got leave from the Army to continue their studies interrupted by the War, while some have gone there from the U.S.S.R. or after their escape from German prison camps. The Paderewski Hospital is devoted entirely to Polish patients and to the training of medical students and graduates. In addition to this hospital provision, valuable work has been done by a Polish sanatorium for tuberculous cases in Great Britain. Established at the end of 1942 at Gallowhill Hall, this sanatorium has now a capacity of one hundred beds and can carry out the best treatment. The majority of Polish cases of tuberculosis are, however, still distributed throughout British hospitals and Polish military hospitals. The percentage of tuberculosis, says Dr. Spitzer, is higher now among

Poles in exile than it was in Poland before the War, so that there is urgent need of the developments which are contemplated.

Something of what is happening in Poland now may be imagined by reading between the lines of the extract from a secret report on the condition of the Polish children which this journal publishes. At all ages the theoretical rations of Polish children are half the theoretical normal calorie value, while those of Nazi children are well above this norm. In practice, the writer of this report states, the quantity and quality of the food fluctuate; sometimes it is reduced to nil. In the Rodom district, for example, the children of the landworkers do not get any ration cards at all. Almost everywhere the distribution of milk to children under three has been suspended. The writer concludes that the rations show a deficiency of 90 per cent of fats, 80 per cent of albumins and 50–60 per cent of carbohydrates. It is not surprising that infectious diseases and "a frightening mortality", with a high percentage of tuberculosis, which is increasing, and of heart weakness are evident among Polish children. These conditions are, as recent articles in the *British Medical Journal* and *The Lancet* and discussions in the Houses of Lords and Commons have shown, reproduced in most of the occupied countries. It is easy to exaggerate them; but we should not commit the graver error of underestimating their consequences. The agricultural basis of European rehabilitation is clearly recognized, and Polish veterinarians have for long been co-operating with British veterinarians in the reconstruction of Polish veterinary medicine. An article on this, and others on the improvement of Polish milk hygiene and on the eradication of tuberculosis from Polish cattle, 25–50 per cent of which are, Dr. Mglej tells us, tuberculous, indicate that this aspect of the future is not being neglected.

Classification in Biology

THE question is often asked by students as to which is the 'right' classification of a group of animals. Mr. K. H. Chapman, lecturer in zoology, Rhodes University College, Grahamstown, South Africa, directs attention to certain ideas that must be kept in mind when considering schemes of classification from this point of view in a communication to the Editors which is summarized below. Although such conceptions have been put forward before, there persists so much misconception about the nature and purpose of systematics in biology, not only among students but also among biologists themselves, that it is necessary to re-emphasize these points. It is probable that no classification is right or definitive because there is no real classificatory system outside ourselves that it is only necessary for us to discover. In most groups it is obvious that we can only deal with survivors; and even where fossils do exist, they are unselected members of the group from this point of view. Thus it follows that natural classification is an unfortunate term. Living animals do not fall into true and equivalent groups even though we arbitrarily place them in such, and consequently we can only regard classification as a convenient tool with which to deal with a large mass of material, and it does not have a natural existence of itself. It is only necessary to compare the species, genera and other groups of insects with the similarly named categories in other phyla to realize their non-equivalence. The species, whatever it may be, also must be regarded as a dynamic and not a static unit, and any living group may, in the course of time, become something different. The question of polyphylletic origins also arises; for example, W. A. Herdman suggested that the compound ascidians are an assemblage of groups evolved from different groups of the simple ascidians which had independently assumed the colonial habit of growth. Any classification is to be regarded as an expression of a scale of values which indicates, in the opinion of its proposer, the relative nearness or farness of two or more groups with respect to one another.

The British Bryological Society

FEW associations of naturalists have been originated by advertisement, but such was the genesis of the Moss Exchange Club. The Rev. C. H. Waddell first advertised in *Science Gossip* in December 1895 and, from the twenty-three favourable replies, founded the Club in the following year, when 2,077 specimens were distributed. It remained an association depending very largely on postal contact until 1922, when the need for closer personal association in field meetings led to the formation of the British Bryological Society. Miss Eleonora Armitage has collated the annual reports of both Club and Society into a short pamphlet (Miss Armitage, Dadnor, Ross). She was president at the Society's last meeting in 1939, and this review should serve the purpose of sustaining the collective interests of bryologists until more stable times allow a resumption of their activities. Several census lists of British bryophytes have been published, from the York Catalogue, compiled by J. A. Wheldon in 1889, to the latest taxonomic indexes for mosses, compiled by J. B. Duncan in 1926, and for hepatics, by A. Wilson in 1930. The taxonomy of mosses and liverworts is now largely established, but many bryological matters still require elucidation. Perhaps the post-war period will provide opportunities for detailed ecological studies —the relation of a moss or liverwort to its substrate, its reactions with other plants, and particularly of its unique physiology, which allows a special phenology of reproduction not possessed by any other kind of plant.

Work of the League of Nations

THE report on the work of the League of Nations during 1942–43, submitted by the Acting Secretary-General, in addition to an introductory section giving a useful survey of proposals for future world organization, contains chapters on economic, financial and transit questions, on questions of a social and humanitarian character, on questions of a legal and administrative character and on the Library of the League. The work of the League on the first group of questions is reflected chiefly in a series of reports which have already been noticed; but in regard to the second group, the report affords strong evidence that whatever views may be held as to the continuance of the League as a co-ordinating machinery in political affairs, its technical organizations should be retained as part of the functional apparatus set up in any future world organization.

The Health Section has concentrated its attention during the year on the present food scarcity, and on malnutrition and the danger of epidemic outbreaks in Europe. A comprehensive study of the trend of morbidity and mortality of European countries in relation to food shortage is shortly to

appear in the *Bulletin of the Health Organisation*. The Organisation has also been requested to determine which food elements are most acutely lacking in the present dietary of enemy-occupied countries, so that foods prepared by the Allied Food Relief Organization should, in the form of adequate complement rations, compensate present deficiencies. Information on the health situation in Europe was summarized in a series of notes on the prevalence, trend and probable course of typhus fever, cerebro-spinal meningitis, enteric fever, scarlet fever, smallpox, poliomyelitis, etc., and typhus fever was also the subject of a special study. The Singapore Bureau functioned until less than a week before the occupation of Singapore by the Japanese in January 1942. The activities of the Health Information Service have been maintained, and a study on the significance of names of communicable diseases in various languages was amplified and extended to form the basis of a comprehensive glossary in twenty-four languages of the communicable diseases. Research has continued on several subjects on the agenda of the Permanent Commission on Biological Standardization, including the nature of the toxins produced by the tetanus germ and by *Bacillus perfringens*, one of the agents of gas gangrene.

In regard to the Control of the Drug Traffic, international supervision has been impaired by the deterioration of communications, and difficulties in obtaining the necessary supplies have in some South American countries led to plans to produce raw opium and to manufacture drugs. The report directs attention to the danger that an excess of manufacture over legitimate needs may follow, and to the importance of taking, as soon as possible, all necessary steps to restore the full measures of control as they existed before the War. Work has already commenced on a post-war planning programme in this field, which includes a study and review of present national and international systems of control, with the view of suggesting improvements, and a study has been made of the legal position of drug addicts and current methods for treatment of addiction. The collections of the Library comprised about 318,200 volumes at the end of 1942, and in view of the exceptional facilities for work which the documentary material available will offer after the War, the secretariat is studying the means by which a gradual return to normal conditions may be effected.

Smithsonian Institution : Annual Report

THE report of the Secretary of the Smithsonian Institution for the year ending June 30, 1943, includes the report of the secretary and the financial report of the executive committee of the Board of Regents, together with the usual reports of the United States National Museum, the National Gallery of Art, the National Collection of Fine Art, the Freer Gallery of Art, the Bureau of American Ethnology, the International Exchange Service, the Astrophysical Observatory and on the Library. The secretary's report points out that all personnel and facilities of the Institution and its branches were made available and extensively used in the prosecution of the War, although the normal activities were kept alive to the extent of continuing observations the cessation of which would leave permanent gaps in records essential for future investigations and of maintaining and caring for the national collections. All other research and exploratory projects not required for the orderly resumption of cultural activities after the War have been suspended, except those activities relating to closer cultural co-operation with the other American republics. Much of the Institution's contribution to the war effort is of an indirect nature. More than a thousand recorded inquiries had been answered up to the close of the fiscal year, and a list of selected examples tabulated by the War Committee shows not only the wide range of these questions but also the extent to which modern total war depends on scientific knowledge.

War research projects have also been concerned with many different branches of science, including anthropology, biology, geology, physics and meteorology, and these projects occupied almost the whole time of the instrument and mechanical shops of the Astrophysical Observatory, the Division of Radiation and Organisms and the Division of Engineering, as well as of numerous individual members of the scientific staff. With regard to inter-American co-operation, the report refers to the organization of an Inter-American Society of Geography and Anthropology, with membership open to scientific workers anywhere in the hemisphere. More than 700 members have already been enrolled. The first part of a check list of the coleopterous insects of Mexico, Central America, the West Indies and South America is now in the Press as a bulletin of the National Museum. A prediction of the march of solar variation during 1939–45 based on periodicities revealed by the solar-constant values published in vol. 6 of the *Annals of the Astrophysical Observatory* shows that the years 1940–47 will be the most important years to study the sun's variations since the early twenties, and for this reason every effort has been made to keep the three field observatories in Chile, California and New Mexico in operation. With regard to the international exchanges, the report records that the Office of Censorship lifted in January 1943 the ban imposed in April 1942 on sending abroad the *Congressional Record* and the *Federal Register*.

Office Organization in Engineering Works

A BOOKLET issued by the British Standards Institution, "Office Organisation and Practice" (B.S.1100; Part 10; 1943), states in some detail the underlying principles of good office management and clerical organization, and gives practical guidance as to the installation of a system and the technique of office and clerical organization. It is addressed primarily to engineering firms of 250–1,000 employees with offices of 20–100 clerks, but the large amount of basic information on office practice condensed and set out simply in this booklet should be equally valuable to smaller firms in all branches of industry. Sections are included on the planning of systems ; the design and use of forms ; the use and selection of machines and other devices, with an appendix listing suppliers ; accommodation, lay-out, lighting and heating requirements of offices ; personnel organization, including the grading of jobs and standards of performance and incentives ; training, selection, co-ordination and control of staff, and methods of inspection of work. Typing is dealt with in a separate section including both selection and training and the pool system, while a further section deals with communications, both inward and outward mail, the use of telephones and messengers. There is a short

section on filing and another on sales invoicing. A short bibliography and an index add to the value of the publication.

Institution of Electrical Engineers : Annual Report

ACCORDING to the report for the year 1943–44 of the Council of the Institution of Electrical Engineers, total membership on March 31, 1944, numbered 24,558, and of those there were 11,924 corporate members; 2,944 elections to all classes of membership were made during the previous twelve months. During the year 562 meetings were held in London and at the local centres. The Wireless Section held fifteen meetings, the Measurements Section eight, the Transmission Section eight, the Installations Section seven, and there were six informal meetings. There are nine students sections. Post-war planning has received close attention at the hands of the committee appointed for the purpose, and reports have been published on "Education and Training for Engineers", the "Organization of Post-War Electrical Research", and on "Electricity Supply, Distribution and Installation." A report on "Electricity in Post-War Building" has been completed by the Electrical Installations Committee and is being published by H.M. Stationery Office. The Council's report also deals with various phases of the Institution's war effort, with technical investigations, joint activities with other institutions, and with the subject of education. The revised eleventh edition of the Regulations for the Electrical Equipment of Buildings has been issued during the year.

Monthly Astronomical Newsletter

BART J. BOK, Harvard Observatory, prepares a *Newsletter* each month for the American Astronomical Society which is intended to keep scientific societies informed about progress in various branches of astronomy during the disruption of exchange of information. Some of the notes are duplicated in other publications, such as *Sky and Telescope*, and by Science Service. The present issue, No. 17, contains brief references to papers and notices in *Harvard Announcement Cards*, the *Astrophysical Journal*, *Popular Astronomy*, etc. A considerable portion is devoted to a review of contributions by Dr. N. T. Bobrovnikoff and others on the physical properties of comets.

The Night Sky in July

FULL moon occurs on July 6d. 04h. 27m. U.T., and new moon on July 20d. 05h. 42m. The following conjunctions with the moon take place: July 18d. 08h., Saturn 1° N.; July 22d. 01h., Mercury 0·7° S.; July 22d. 20h., Jupiter 2° S.; July 23d. 11h., Mars 2° S. The following conjunctions in addition to the above also take place: July 5d. 08h., Mars in conjunction with Jupiter, Mars 0·2° N.; July 10d. 04h., Mars in conjunction with Regulus, Mars 0·7° N.; July 20d. 12h., Jupiter in conjunction with Regulus, Jupiter 0·5° N.; July 28d. 08h., Mercury in conjunction with Regulus, Mercury 0·01° N.; July 29d. 17h., Mercury in conjunction with Jupiter, Mercury 0·7° S. Occultations of stars brighter than magnitude 6 are as follows: July 2d. 21h. 20·9m., θ Libr (D); July 30d. 21h. 57·7m., χ Ophi. (D). The times refer to the latitude of Greenwich and (D) means disappearance. Mercury is in inferior conjunction on July 1. At the middle of the month the planet sets 50m. after the sun and at almost the same interval at the end of July. Venus is too close to the sun to be conveniently observed until late in the month. On July 31 the planet sets less than half an hour after the sun. Mars, in the constellation of Leo, can still be observed as it sets 2h. after the sun at the beginning of July and 1h. 10m. after sunset on July 31. Jupiter, in the constellation of Leo, is drawing near the sun, setting only 50m. after sunset at the end of July. Saturn is no longer visible. The earth reaches aphelion on July 3 when its distance from the sun is 94,560,000 miles. An annular eclipse of the sun, invisible at Greenwich, takes place on July 20. At Bombay the magnitude of the eclipse is 0·95, at Hong Kong 0·90, and at Madras 0·80.

Announcements

THE following elections to the Royal Society have been made: fellow of the Royal Society under Statute 12: the Right Hon. S. M. Bruce, High Commissioner for Australia in London. Foreign members: Dr. O. T. Avery, bacteriologist, member of the Rockefeller Institute, New York; Prof. M. Lugeon, professor of general geology and stratigraphy in the University of Lausanne; Prof. The Svedberg, professor of physical chemistry in the University of Uppsala; Prof. N. E. Svedelius, professor of botany in the University of Uppsala; Prof. S. Timoshenko, professor of engineering mechanics in the University of Michigan.

THE director of the Chinese National Central Library has offered to provide British scholars with Chinese material for specialist researches, and to arrange for its translation into English if this is desired. The Library will also forward lists of books available to interested institutions in Great Britain. The British Council has undertaken to act as intermediary on the British side; all inquiries should be addressed to the Director, Books Department, British Council, 3 Hanover Street, London, W.1.

Two prizes of 200 dollars each, offered by Mr. A. Cressy Morrison, to be known as the A. Cressy Morrison Prizes in Natural Science, will be awarded in December 1944 by the New York Academy of Sciences. Papers, which must embody the results of original research not previously published, must be submitted on or before October 1, 1944, to the Executive Secretary of the New York Academy of Sciences, at the American Museum of Natural History, Central Park West at 79th Street, New York, N.Y.

THE University of Birmingham is to award Anglo-American studentships to encourage research in some branch of petroleum technology. These studentships will normally be awarded for one year, but may be renewed for a second year, the value of the award being £225 for the first year and £250 for the second year, if renewed. They are open to graduates of the University of Birmingham and science graduates of other universities. Applications, which should include a statement of age, academic qualifications and career, should be submitted to the Registrar of the University of Birmingham by July 15. Applicants must also submit the names of two referees.

ERRATUM. In the communication "Thermal Fatigue in Metals" by W. Boas and R. W. K. Honeycombe printed in NATURE of April 22, p. 494, the illustration has been inverted: photomicrograph d should be a; c should be b; b should be c; and a should be d.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

New Components of the Vitamin B Complex

AN attempt to prepare a concentrate of folic acid from liver by the method of Hutchings *et al.*[1] resulted, as already noted in a recent review[2], in the preparation of a fraction probably containing folic acid, together with another fraction soluble in chloroform, which likewise stimulated the growth of certain micro-organisms. A second chloroform-soluble fraction with similar properties has now been obtained. All three of these fractions stimulate the growth of *Lactobacillus helveticus* and *Streptococcus lactis* R 8082, but not that of *Lactobacillus arabinosus* 17/5. Although the growth-promoting properties of the chloroform-insoluble fraction are probably due to folic acid, the chloroform-soluble fractions are believed to contain new factors not previously described.

At first, an alcohol precipitate obtained as a by-product in the manufacture of commercial liver extracts was used as the starting material for the preparation of these fractions; but later, it was found more convenient to prepare the chloroform-soluble factors from the liver extract ('Examen') itself, manufactured according to the method of Laland and Klem[3]. This was subjected to the following fractionation procedure: extraction with chloroform at *p*H 3, concentration of the washed extract *in vacuo* to dryness; solution of the residue in water; adsorption on 'Decalso' at *p*H 4·5; elution with hot 10 per cent sodium chloride solution; extraction of the eluate with phenol at *p*H 3; and transference of the activity to water by addition of ether.

The eluate and the combined 'Decalso' filtrate and washings were each concentrated *in vacuo* to the original volume of the 'Examen'. In this way, two fractions were separated, an eluate and a filtrate factor.

Both concentrates stimulated the growth of *L. helveticus* and *S. lactis* R when added in place of a folic acid concentrate, but in different ways. With *L. helveticus*, the presence of both factors produced a synergistic effect, whereas with *S. lactis* R, the effect was additive. The concentrates were added at levels of 0·5, 1·0 and 2·0 and occasionally at 4 ml./10 ml. to a basal medium which was a modification of the basal medium described by Landy and Dicken[4]. At levels of 2–4 ml./10 ml. of medium, the filtrate factor alone appeared to be a complete substitute for folic acid for both organisms, but a mixture of the filtrate and eluate factors could replace folic acid at much lower levels (0·1–0·5 ml./10 ml. of medium). In the case of *S. lactis* R the effect appeared to be purely additive, but with *L. helveticus* the effect was greater than the sum of the growth-stimulating effect of each. Two typical results are given below, expressed as the amount of standard alkali necessary to neutralize the acid produced:

L. helveticus. Incubation for 48 hr. at 37°.

Chloroform-soluble filtrate factor

ml. concentrate in 10 ml. medium	Blank	0·5	1·0	2·0
ml. 0·1 *N* NaOH	0·1	2·1	4·5	6·8

Chloroform-soluble eluate factor

ml. concentrate in 10 ml. medium	Blank	0·5	1 0	2·0
ml. 0·1 *N* NaOH	0·1	0·9	0·9	0·9

Chloroform-soluble filtrate + eluate factors

ml. concentrates in 10 ml. medium	Blank	0·1 + 0·1	0·5 + 0·5	1·0 + 1·0	2·0 + 2·0
ml. 0·1 *N* NaOH	0·1	2·6	4·5	8·3	9·9

The synergistic effect of the two factors together is clear from these results.

S. lactis R incubated for 72 hr. at 30°.

Chloroform-soluble filtrate factor

ml. concentrate in 10 ml. medium	Blank	0·5	1·0	2·0
ml. 0·05 *N* NaOH	0·1	2·0	2·8	5·4

Chloroform-soluble eluate factor

ml. concentrate in 10 ml. medium	Blank	0·5	1·0	2·0
ml. 0·05 *N* NaOH	0·1	1·4	1·9	2·7

Chloroform-soluble filtrate + eluate factors

ml. concentrates in 10 ml. medium	Blank	0·1 + 0·1	0·5 + 0·5	1·0 + 1·0	2·0 + 2·0
ml. 0·05 *N* NaOH	0·1	2·1	3·2	6·3	8·2

Here the influence of the two factors is apparently additive.

Neither of the chloroform-soluble factors was destroyed by nitrous acid, by acetylation with acetic anhydride in sodium hydroxide solution (at room temperature), or by benzoylation with benzoyl chloride and sodium hydroxide solution.

The chloroform-soluble factors appear to be different from folic acid and indeed from other similar factors described in the literature, which are all reported to be insoluble in the common organic solvents, except glacial acetic acid.

The full experimental evidence will be published in due course.

An 'Incomplete' Antibody in Human Serum

A STUDY of the properties of mixtures of different types of human anti-*Rh* sera has led to the recognition of what appears to be an incomplete antibody. The research arose out of a suggestion by Prof. R. A. Fisher that this technique might throw some light on the problem of antibody absorption.

Human anti-*Rh* serum of the type called by Wiener "standard" agglutinates red cells of the gene Rh_1 and also those of Rh_2. 'Anti-Rh_1' serum agglutinates the former cells but not the latter[1,2]. If, however —and this was the observation that started the present work—cells of the genotype Rh_2Rh_2 or Rh_2rh are added to a mixture of these two sera, the expected agglutination due to the standard anti-*Rh* serum does not occur. It was then found that the sera need not be mixed, for if the Rh_2 cells are suspended in anti-Rh_1 serum—which causes no agglutination—and after a few minutes are separated from the serum, washed and re-suspended in saline, then these treated cells can no longer be agglutinated by standard anti-*Rh* serum.

In January of this year Fisher drew up the following formulation of the relationships found in the Rhesus factor, designed to distinguish the three categories, antigens, genes or allelomorphs and antibodies for which provision must be made in a satisfactory notation.

Name of serum:		Anti-*Rh*$_1$	*St*	Anti-*Rh* Standard	Anti-*Rh*$_2$	Not yet found	
Antibody present:		Γ	γ	Δ	H	δ	η
Genes							
Rhz	*CDE*	(+)	(—)	(+)	(+)		
Rh$_1$	*CDe*	+	—	+	—		
Rhy	*CdE*	(+)	—	(—)	+		
Rh'	*Cde*	+	—	—	—		
Rh$_2$	*cDE*	—	+	+	+		
Rh$_0$	*cDe*	—	+	+	—		
Rh"	*cdE*	—	+	—	+		
rh	*cde*	—	+	—	—		

Those reactions not yet determined serologically are given in brackets.

The three forms of allelomorphic antigens are arbitrarily denoted by C, c, D, d, E, e, chosen to avoid confusion with any symbols so far used. The antibodies with which these react are denoted by corresponding Greek letters. These single letters refer to antigens and their corresponding antibodies only. Every gene of the system seems to be associated with a selection of three antigens from these three pairs. The system thus predicts an eighth allelomorph, *Rhz*, which could not be recognized in a single individual, but could be identified in a favourable pedigree. It also suggests the possibility of two more antibodies not yet known reacting with d and e respectively.

Wiener[1] has supposed that the presence of the *Rh*$_1$ gene results in there being two "partial antigens" on the red cell (C and D of the table), and our recent work with *St* and other sera seems to make three parts necessary to the total antigen resulting from the *Rh*$_2$ gene, namely, c, D and E.

It is only one of these three antigens in the *Rh*$_2$ cells, called D in the table, which is being blocked by the anti-*Rh*$_1$ serum. E and c are left uncoated and ready for agglutination.

	Rh$_2$ cells untreated				*Rh*$_2$ cells coated with anti-*Rh*$_1$ serum			
Serum dilutions	1/1	1/2	1/4	1/8	1/1	1/2	1/4	1/8
Anti-*Rh*$_1$ serum (Γ)	—	—	—	—	—	—	—	—
Standard anti-*Rh* serum (Δ)	+	+	+	+	—	—	—	—
St serum (γ)	+	+	+	+	+	+	+	+
Anti-*Rh*$_2$ serum (H)	+	+	+	+	+	+	+	+

The coating of this same D antigen in *Rh*$_1$ cells can be demonstrated, but first it is necessary to remove the agglutinin (Γ) in the anti-*Rh*$_1$ serum for *Rh*$_1$ cells. This was done by absorption of the serum by *Rh'rh* cells which remove the agglutinin but not the coating factor, since these cells contain C but not the coatable antigen D. With the resulting absorbed serum, cells of the genotype *Rh*$_1$*Rh*$_1$ can be coated without agglutination confusing the result. There is no blocking of the antigen C in *Rh*$_1$ cells.

Absorption with untreated *Rh*$_2$ cells diminishes the agglutinin titre of standard anti-*Rh*, (Δ), anti-*Rh*$_2$ (H) and *St* (γ) sera. Absorption with coated *Rh*$_2$ cells diminishes the titre of anti-*Rh*$_2$ and *St* sera but not that of standard anti-*Rh* serum. Thus, absorption experiments confirm that in *Rh*$_2$ cells it is only the antigen D which is being blocked, E and c being left free.

The coating factor may be looked on as the standard anti-*Rh* serum antibody (Δ), which can combine with its appropriate antigen, but is defective in that it is not a suitable partner for the second stage of the antigen-antibody reaction which results in agglutination of the cells. It may be called an incomplete antibody (Δ'). Varying salt concentrations failed to produce agglutination of the coated cell suspensions, so did variations in the pH.

The incomplete standard anti-*Rh* antibody (Δ') has been found in good strength in four anti-*Rh*$_1$ sera (from *Rh* negative mothers) and in a weak amount in our remaining anti-*Rh*$_1$ serum (from an *Rh* negative mother). With the removal of the incomplete antibody, these five sera gained no fresh agglutinating range; they did not, for example, then behave as anti-*Rh'* sera. In other words, there is no complete standard anti-*Rh* serum antibody present which is being masked by the presence of the incomplete form of this antibody.

One standard anti-*Rh* serum in our collection contains the incomplete antibody (Δ') as well as the complete agglutinin (Δ). Titration results with this serum and *Rh*$_1$ or *Rh*$_2$ cells had previously given what was a puzzling and unique appearance—weak reactions, with intervening negatives, continuing up to a high dilution (1/1,000). Preliminary absorption with, say, *Rh*$_2$ cells removes the incomplete antibody leaving the normal antibody, which now gives strong reactions up to the same titre with more of the same *Rh*$_2$ cells. It seems as if the incomplete antibody wins the race for antigen.

Incomplete antibodies have been looked for but not found in three *St* sera, four anti-*Rh*$_2$ sera, one standard anti-*Rh* serum, two sera from normal *Rh* negative donors, and eleven sera from normal *Rh* positive donors. The appropriate antigen D in all cells so far tried has been coatable; the cells were *Rh*$_1$*Rh*$_2$ (1), *Rh*$_1$*Rh*$_1$ (3), *Rh*$_1$*rh* (3), *Rh*$_2$*rh* or *Rh*$_2$*Rh*$_2$ (6) and *Rh*$_0$*rh* (1). The incomplete antibody can be removed from serum by appropriate but not by inappropriate (for example, *rhrh*) cells, nor by saliva from an *Rh*$_1$*Rh*$_1$ A_1B secretor. Heating to 56° C. all the sera involved made no difference to the reactions.

I do not know of any similar phenomenon in hæmagglutination or hæmolysis. The inhibition by normal serum of the tissue hæmolysis of red cells recently reported by Magraeth, Findlay and Martin[3] is evidently of a very different nature. The inhibitor described by these workers was not species specific, whereas the incomplete antibody now being described is specific down to one antigen.

In bacterial agglutination a more striking resemblance is found in the agglutinoid phenomenon studied by Shibley[4]. The most obvious differences are that agglutinoid was made by partial heat denaturation of the serum and showed itself only as a zone of inhibition followed in higher dilutions by normal agglutination; whereas in the anti-*Rh*$_1$ sera, which had not been heated but stored at − 20° C., all the standard anti-*Rh* antibody was in the incomplete form while all the anti-*Rh*$_1$ antibody was in the complete form. The behaviour of anti-*Rh* sera, heated to 65–70° C., is now being investigated.

Very recently a sixth anti-*Rh*$_1$ serum has been found, locally. The incomplete antibody was present in good strength immediately after taking the blood.

Rh Antibodies in Human Sera: a New Variety

Human sera containing several varieties of *Rh* antibodies have been described[1]. These may be distinguished one from another by their reactions with *Rh*-positive cells, particularly with the rare types *Rh'* and *Rh"*. The reactions are shown below.

Serum	Cells			
	Rh_1	Rh_2	Rh'	Rh''
Anti-*Rh*	+	+	—	—
Anti-*Rh'*	+	+	+	—
Anti-*Rh"*	+	+	—	+
Anti-Rh_1	+	—	+	—
Anti-Rh_2	—	+	—	+
Serum-*Hi*	+	+	+	+

The sera anti-*Rh'* and anti-*Rh"*, confirming previous work, have been shown to contain two agglutinins: anti-*Rh* and anti-Rh_1 in the former case, and anti-*Rh* and anti-Rh_2 in the latter. Each individual anti-*Rh'* or anti-*Rh"* serum varies in its content of component agglutinins. In many cases the relative strengths of these agglutinins may be judged by titration of the original serum with the cell types shown in the table.

A maternal serum (*Hi* in table) was studied which reacted with nearly all *Rh*-positive cells. This mother had given birth to three children but none had survived. The mother was *Rh*-negative and the father subtype Rh_2.

Absorption of this serum with certain *Rh*-positive cells has shown that it contains three agglutinins, anti-*Rh*, and two others resembling in their activity anti-Rh_1 and anti-Rh_2. The paternal genotype is unknown but it may be Rh_0Rh_2, and the immunizing effect of fœtal erythrocytes of genotype Rh_0rh may be responsible for the appearance in this maternal blood of the agglutinins which react with *Rh'* cells. This is supported by the fact that anti-*Rh'* agglutinins have been found in the serum of a mother, Group *Rh"*, whose child, genotype Rh_0Rh'', was affected with hæmolytic disease.

The serum *Hi* reacts very strongly with cells of genotype *Rh'Rh"*. This genotype has been seen four times, twice in siblings.

Sulphur-containing Amino-Acids and Jaundice

IN connexion with part of the recent note of Beattie and Marshall[1], which may give the impression that methionine has a strikingly beneficial effect upon patients suffering from so-called "post-arsphenamine" jaundice, we feel that the time has arrived to report very briefly some of our own results in a trial on similar lines started by us more than a year ago. Promise of its success was indicated by the literature; and it was felt that every therapeutic possibility should be explored in view of the high incidence of this serious complication.

More than 450 cases have now been studied, and the progress of individual cases has been judged both clinically and by determination of the rate of fall of the serum bilirubin level. Of these cases, more than three hundred had to be excluded from the present analysis because the jaundice was too slight or too long established for satisfactory demonstration of a therapeutic effect. The ultimate assessment has been confined therefore to the hundred and fifty most severe cases coming under observation early in the disease. Some of these were treated with cysteine (as the ester hydrochloride), 2 gm. daily, some with methionine, 2·5 gm. or 5 gm. daily, and some with casein, 60 gm. daily. Throughout the trial an appropriate proportion of cases was set aside as controls. All patients were kept in bed, and received the same diet. There were 57 controls, 41 cases treated with cysteine, 33 with methionine, and 19 with casein. A brief summary of the results is set out in the accompanying table.

	Total no. cases	Mean no. of days for serum bilirubin to fall below 4 mgm. %, with no subsequent exacerbation, counted from the onset of jaundice
Control	57	25·8
Casein	19	32 9
Cysteine	41	21·3
Methionine	33	19·7

PERCENTAGE OF CASES IN WHICH THE SERUM BILIRUBIN FELL TO BELOW 4 MGM. %, WITH NO SUBSEQUENT EXACERBATION, IN THE PERIODS STATED, COUNTED FROM THE ONSET OF JAUNDICE.

	Less than 14 days	14–20 days	21–27 days	More than 27 days	% down in under 3 weeks
Control	10	23·5	29 5	37	33·5
Casein	10 5	26	10·5	52	36·5
Cysteine	12	51	12	24	63
Methionine	22·5	48·5	22·5	6 5	71

The results given in the table have been examined statistically; they show that both cysteine and methionine had a significant but not remarkable effect on the course of the jaundice. These findings confirmed the clinical impression that the benefit, although definite, was not sensational under the conditions of these tests. The casein had no action. In view of the known methionine content of the latter, it is surprising that no effect was obtained, and it is hoped that further work will provide an explanation of the apparent discrepancy. A full report of this work is now being prepared for publication.

(This work was made possible by Major-General L. T. Poole and Brigadier T. E. Osmond, and by the willing co-operation of a large team of workers, among whom we may mention Major Lane for estimations of serum bilirubin, Dr. Stocken and Messrs. Whittaker and Spray (Department of Biochemistry, Oxford) for preparation of natural cysteine (from hair), the Ministry of Supply for the supply of synthetic methionine, and the Statistical Committee of the Medical Research Council.)

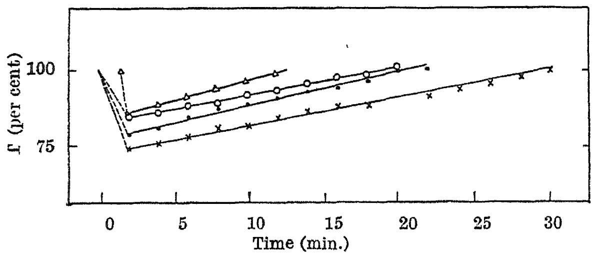
Adenosine-triphosphate Initiating Contraction and Changing Bi-refringence in Isolated Cross Striated Muscle Fibres

SINCE previous investigations[1] have demonstrated close relationship between myosin and adenosine-triphosphate, it seemed of interest to investigate the action of adenosine-triphosphate and related phosphorus compounds on living isolated muscle fibres.

So far we have used adenosine-triphosphate (isolated from rabbit muscle and purified several times through the mercury and barium salts), inorganic triphosphate, pyrophosphate and orthophosphate. All substances were used in iso-osmotic solutions of pH 7·3, part of the sodium chloride in the Ringer solution being replaced by an equivalent amount of the sodium salts of the substances in question.

Micro-application with micropipette and micro-manipulator[2] of adenosine-triphosphate in amounts of 2–3 $\times$ 10^{-1} μgm. on non-curarized and curarized muscle fibres initiates repeated, twitch-like contractions. These are accompanied by action potentials. Repeated application (with washing out in between) has the same effect.



DECREASE AND RESTITUTION IN PHASE DIFFERENCE (Γ) (ORDINATE) AFTER ELECTRIC TETANIC STIMULATION, —△—△—.

—o—o—, after application of 2·85 $\times$ 10^{-6} mol./ml. aden. triphos.

—·—·—, ,, ,, ,, 4·25 $\times$ 10^{-6} ,, ,, ,,

—×—×—, ,, ,, ,, 5·7 $\times$ 10^{-6}. ,, ,, ,,

Bi-refringence, examined by means of the Babinet compensator[3], falls 20–30 per cent after application of adenosine-triphosphate (1·2–7·3 $\times$ 10^{-6} mol./ml.) and recovers spontaneously in the course of 15–20 min. The degree of decrease and the duration of recovery depend on the concentration applied, and the time course corresponds closely to that observed after tetanic electric stimulation (see graph).

Cozymase (60 per cent preparation) in concentrations of 0·05–0·5 mgm./ml. is without effect either on the mechanical response or bi-refringence.

Preliminary experiments with inorganic *triphosphate* (6·1 $\times$ 10^{-6} mol./ml.) likewise show release of contraction of a more contracture-like type, the decrease in bi-refringence being only a quarter to a third of that occurring after application of adenosine-triphosphate.

Pyrophosphate in concentrations of 6·7–9·8 $\times$ 10^{-6} mol./ml. initiates contraction, and bi-refringence exhibits an irreversible fall of *c.* 40 per cent. Lower concentrations without releasing mechanical responses are accompanied by a decrease in bi-refringence the partial recovery of which takes more than 40 min.

Orthophosphate in concentrations of 2·5 $\times$ 10^{-5} mol./ml. likewise initiates contracture-like contractions, but no changes in bi-refringence occur.

The experiments indicate that: (1) In spite of the fact that different investigators[4] find that muscle membranes are impermeable to adenosine-triphosphate, it may react directly or indirectly with contractile and doubly-refracting elements. (2) Adenosine-triphosphate normally could be an agent of contraction, while adenosine-triphosphate present in muscle cannot be in immediate contact with the contractile elements due either to differences in local distribution or to the presence of a non-reactive compound. Addition of adenosine-triphosphate thus would correspond to the establishment of contact between adenosine-triphosphate and contractile elements otherwise initiated by the nervous impulse. (3) In contrast to findings with pure myosin, phosphorus compounds other than adenosine-triphosphate may release contraction and cause changes in bi-refringence.

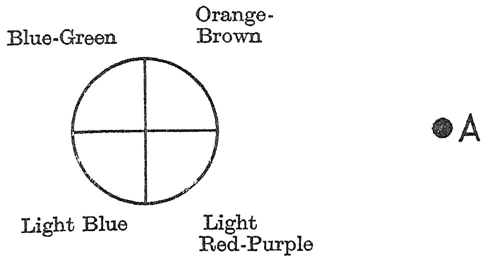
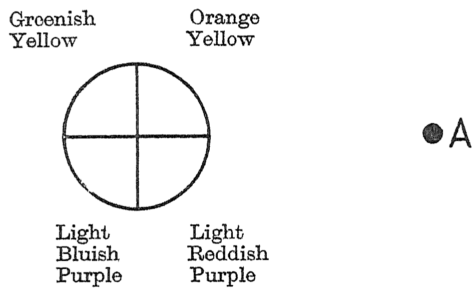
Colour of Small Objects

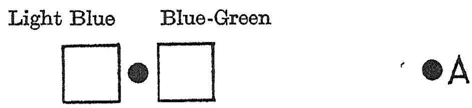
IF a circle, 2 cm. in diameter, is divided into quadrants and coloured as in Fig. 1, placed on either a black or white ground, and then viewed with one eye from a distance of about 3 m., it will be found that there is considerable difficulty in distinguishing the green from the light blue on one hand and the orange-brown from the light red-purple on the other, so long as the brightnesses of the fields are made as equal as possible. There will be no difficulty in distinguishing the green from the orange, provided that the observer is not red-green colour-blind in the sense that he habitually confuses such colours, and the circle will appear to be divided into two halves, right and left. Red-green colour-blind observers see the circle as uniform, or they may be able to separate the quadrants on subtle brightness differences.

Similar effects will be observed if the quadrants are coloured as in Fig. 2. The result in this case is even more striking since, if the circle is viewed at close range, it divides naturally into a yellow and green upper half and into a purple lower half. At a distance it divides vertically into a greenish-grey left half and a brownish-grey right half. It will be found that each particular green has its corresponding blue or mauve with which it is confused, and each yellow, orange or brown has its own particular reddish-purple.

In both cases, if the eye is focused not on the centre of the circle directly but on the point A, about 4 cm. from the centre of the circle, then all the quadrants stand out in their true colours. The point A may lie upon any radius of the circle. Similar effects are also obtained if the colours are arranged as in Fig. 3, so that they are probably not due to simultaneous contrast or to the overlapping of the images formed on the retina.







It may be inferred from these observations that under these conditions the centre of the fovea is not so good at distinguishing colours as the immediately surrounding area of the retina. The size of the circle is such that it corresponds closely to the so-called rod-free area. Both circle and external fixation point fall within the macula, so that the effect is probably not due to the macular pigment, which would perhaps be expected to act in a rather similar manner by cutting out the blue light. The confusions which occur at the foveal centre are almost exactly those made by the blue-blind person or tritanope[1], so that this area appears to be in some degree dichromatic and lacking in the blue sensation. This is not strictly true, since small objects seen at the centre of the eye may appear blue, but in this area the blue has no unique quality and, as has been shown, is readily confused with certain greens. The retina immediately surrounding the 'rod-free' area is normal and trichromatic.

Recently, the idea was put forward[2] that many of the data concerning colour vision could be explained in terms of two receptors, one the cone and the other the rod; that is, an element depending upon visual purple for its light sensitivity. It was pointed out at the time that this would lead to exactly the type of confusion which the above observations show to occur in the centre of the fovea. This area of the retina therefore perhaps consists of two elements, so far not distinguished histologically, but essentially corresponding to the cone and the rod, with the reservation that in this situation the latter does not accumulate visual purple or become dark-adapted as it does elsewhere in the retina.

Now Granit[3] has found that in the all-rod eye of the guinea pig the shape of the photopic visibility curve differs from that of the corresponding scotopic curve in such a way as to indicate that the retinal element in question acquires a relatively increased sensitivity to blue when light-adapted. If this change in relative sensitivity were dependent upon the 'bleaching' of the large quantities of visual purple in the dark-adapting rods, then this might provide a basis for a possible explanation of human colour vision on the following lines. The centre of the fovea may consist not only of cones but also of rods, the latter depending upon visual purple but not accumulating it. This area would therefore be dichromatic with the properties outlined previously. The rest of the retina would then depend on cones, on rods like those in the fovea, and on 'normal' dark-adapting rods which under photopic conditions would have a higher sensitivity to blue than the other rods and so act as a third receptor. In the red, yellow and green parts of the spectrum, both types of rods would have much the same sensitivity, and it is significant that from about 540 mμ to the red end of the spectrum all spectral colours can be matched by mixtures involving red and green only.

Visibility of Blue and Yellow

IF a pattern consisting of blue and yellow areas be viewed at a sufficient distance by an observer, then, in certain circumstances, the blue is seen as black and the yellow is seen as white, so that the pattern appears to be a black and white one. Factors of importance in determining whether the pattern is seen as blue and yellow or as black and white have been found to be (1) the size of the pattern, (2) the intensity of illumination, (3) the size of the pupil, (4) the exact colours of the yellow and the blue pigments used in the design, (5) the adaptation of the retina, (6) spectral content of illuminant. It is suspected that factors of importance would also be (7) absorption of the eye media, and (8) absorption by the macula lutea.

Some quantitative measurements have been made in respect of factors 1, 2 and 3 (size, intensity and pupil diameter).

TABLE 1. EFFECT OF SIZE OF PATTERN.

3,000 ft. c. 1 mm. pupil

Visual angle (min. of arc)	Blue appeared to be:	Yellow appeared to be
3	Black	White
4	Black	White
5	Bluish Black	White
6	Blackish Blue	Cream
7	Blue	Pale Yellow
8	Strong Blue	Yellow

TABLE 2. EFFECT OF DIAMETER OF PUPIL.

3,000 ft. c. 6 min. of arc

Pupil Diameter	Blue appeared to be:	Yellow appeared to be:
1 mm.	Blackish Blue	White
3 mm.	Blue	Yellow

TABLE 3. EFFECT OF ILLUMINATION.

1 mm. pupil 6 min. of arc.

Illumination in ft. c.	Blue appeared to be:	Yellow appeared to be:
3,000	Blue	Yellow
1	Black	White

Of the three variables which have been tested so far, the change in the size of the pattern has most effect, and the change in the illumination has least effect on the colours seen.

The explanation of the disappearances of the colours appears to be as follows:

Both the blue and yellow pigments are greatly diluted with white light. Owing to the chromatic aberration of the eye, blue and yellow rays cannot be focused simultaneously. Therefore, if yellow images be sharp the blue images form wide diffusion circles; and vice versa. If the yellow images be sharp they fall on areas of retina which are already being illuminated by blue rays, and since these are complementary in colour to the yellow rays, the yellow is greatly diluted with white light, and this dilution increases as the pattern becomes smaller. If the blue images be sharp, it is these which suffer dilution with white light. If the eye be focused at an intermediate position, both blue and yellow images are slightly out of focus and each dilutes the other with white light. This dilution increases as the pattern becomes smaller.

The normal adjustment of the eye is that which produces sharply focused yellow images, and it is, therefore, these which become diluted with white light. In consequence, as the distance between the observer and a given pattern of blue and yellow increases, it is the yellow which first becomes confused with white. The blue images remain undiluted, but they suffer greatly in intensity, as Table 4 shows. It will be seen that down to the visual angle of 12 min. of arc, the fall in intensity of the blue is relatively slight, but that as the visual angle decreases to 3 min. of arc, there is a sudden fall in intensity. It is usually somewhere within this range that the blue is replaced by black.

TABLE 4. EFFECT OF VISUAL ANGLE ON LOSS OF INTENSITY OF GREEN, BLUE AND VIOLET RAYS.

Visual angle (min. of arc)	Percentage loss of intensity for: 5000 A.	4500 A.	4000 A.
24	3	5	9
12	6	10	18
6	12	20	36
3	24	40	62
1·5	48	63	78

The reason for considering the case for rays of 5000 A. is that blue pigments reflect or transmit these almost as much as they do the blue rays and the violet rays.

An increase in the aperture from 1 mm. to 3 mm. adds to the colours of the pigments the colours which are produced by the chromatic aberration of the eye. Consequently both blue and yellow become more visible; as shown in Table 2.

A decrease in illumination from 3,000 to 1 ft. c. decreases the visibility of the colours, because the amount of colour which is above the threshold of the foveal cones at a high intensity of illumination falls below that threshold at a low intensity, as shown in Table 3.

Reproduction of the Woodlouse *Armadillidium vulgare* (Latr.)

DR. H. W. HOWARD, in his valuable studies on this isopod, has shown[1] that the sperms can be stored in the females for at least a year and still remain viable. Further, he records that "Eight virgin females have been isolated from any males for more than two years. In their second year three of these animals produced brood pouches in which eggs could be seen. The eggs, however, in all three cases failed to develop."

On June 29, 1943, I received from Dr. Hamilton E. Quick a number of specimens of this species referable to the variety *rufobrunneus* Cllge. All were adults and females.

One specimen was isolated and kept in a Petri dish. Although examined daily no change was observed until April 2, 1944, when it was noticed that it had developed brood pouches, and on April 22 ova could be distinctly seen with the aid of a lens (× 20). These ova hatched and were liberated on April 27. There were about fifty individuals. The smallest specimens were 1 mm. in length and the largest 1·5 mm. After the first moult, the measurements were 1·10 mm. and 1·15 mm., respectively, and at the end of seven days 1·20 mm. and 1·35 mm.

On April 30 the parent moulted and the progeny took possession of the exuviæ. All are still alive.

Examined on May 23, when just over three weeks old and after the second moult, no sign of red or brown coloration was apparent, and had I not known their history I should have identified them as young specimens of the variety *plumbeus* Lereboullet.

Reaction of Wheat Varieties Grown in Britain to Erysiphe

IN May 1944 a moderately heavy attack of mildew (*Erysiphe graminis*) developed in my wheat yield trial near Maldon, Essex. This trial consisted mainly of experimental breeding material, but since it also contained twenty rod-row plots of each of fifteen important commercial varieties of wheat, an opportunity arose of evaluating these varieties according to their susceptibility or resistance to mildew. Individual rows were classified on a scale of marks according to intensity of infection and the data subjected to an analysis of variance. These data are summarized in the accompanying table, a negative value indicating an attack of less than average severity and a positive value of more than average. Levels of significance are indicated where $P < 0{\cdot}05$.

Certain other commercial varieties were present in the trial in six replications only. Of these, the variety Picardie showed highly significant resistance (score $-6{\cdot}5$, $P < 0{\cdot}001$), but no other departure from the average was significant. There was, however, some indication ($P < 0{\cdot}10$) that the varieties Setter, Steel, Benoist 40, Red Drottning and Squarehead II were resistant, while Robusta, Redman and Vilmorin 29 were susceptible. No variety showed complete immunity to the disease.

Variety	Mildew score	Significance
Juliana	-2.9	$P < 0.01$ resistant
Iron III	-2.7	$P < 0.01$ resistant
Wilhelmina	-2.6	$P < 0.01$ resistant
Desprez 80	-2.5	$P < 0.02$ resistant
Weibull's Standard	-2.0	$P < 0.05$ resistant
Als	-1.3	
Garton's 60	-0.3	
Victor	0	Average
Steadfast	0	
Red Standard	$+0.1$	
Wilma	$+0.2$	
Yeoman I	$+1.5$	
Holdfast	$+2.3$	$P < 0.05$ susceptible
Little Joss	$+3.3$	$P < 0.01$ susceptible
Warden	$+9.3$	$P < 0.001$ susceptible

While mildew is not a factor of major importance in determining yield of wheat under British conditions, these data are of interest since, so far as I am aware, no numerical data of similar scope have previously been published.

White Plumage of Sea-Birds

IN recent correspondence, Craik[1] has suggested that the white plumage of gulls and some other sea-birds might be an advantage to them by rendering them less visible to the fish on which they prey. This interpretation was questioned by Pirenne and Crombie[2], partly on the grounds that it is by no means certain that fish can see birds in the air, whatever their colour. This uncertainty, however, does not arise in the case of birds of prey which hunt over land, for these are undoubtedly seen by their prey. The reactions of other birds to a passing hawk have often been described. It would seem, therefore, that if a white under-surface were of adaptive value to birds which hunt against a background of sky, this form of cryptic coloration would be found among predaceous land-birds. Yet none of the eagles, hawks or owls have the pure white plumage of gulls. Some are certainly very pale on the under-surface, but there does not seem to be a greater tendency among these birds to have light-coloured under-parts than there is among other land-birds.

The Hole Theory of Liquids

RECENTLY, Fürth[1], in a series of papers, has developed the hole theory of the liquid state. A liquid is regarded as a continuum permeated by a large number of holes, the number of holes being comparable to the number of particles in the liquid. The motion of the holes in the material continuum is similar to that of particles in a gas, and the hole theory on this account has a formal similarity with the kinetic theory of gases. A hole has four degrees of freedom, three of translation and one corresponding to a change in its radius. The average period for radial oscillation of holes is found to be

$$\Gamma_0 = 0 \cdot 17 \frac{\rho^{1/2} (kT)^{3/4}}{\sigma^{5/4}},$$

which is of a far smaller order of magnitude than the meanlife Γ of the hole. σ represents the surface tension of the liquid, ρ its density, T the temperature and k is Boltzmann's constant. The meanlife as discussed by Fürth is the time for which a hole lasts before it is destroyed by evaporation of molecules into it. In determining the meanlife, Fürth has neglected the effect of curvature on the rate of evaporation. When this is taken into account, the hole theory affords a simple though, because of its inherent defects, not quantitatively accurate description of the variation of viscosity of liquids with pressure. For example, for pressures smaller than p_2, the internal pressure of the liquid, we have

$$\log_e q = \frac{0 \cdot 54 M}{\rho R T} p,$$

where q is the ratio of the viscosity under pressure p(kgm./cm.^{2}) to that under atmospheric pressure, M the gram molecular weight, and R the gas constant. For most liquids p_i is of the order of 10^3 kgm./cm.^{2}.

It is interesting to observe that (on certain assumptions) the thermal conductivity of a liquid can be connected with the period of the radial oscillations of a hole. We find that the theory requires

$$C \equiv 2\chi/\rho^{1/2} S (\sigma k T)^{1/4}$$

to be a constant and equal to *unity* for all unassociated liquids. In the above expression, χ is the thermal conductivity and s the specific heat per unit mass. The accompanying table gives the observed values for C—the average value for non-metallic liquids is about twice the theoretical value. In the case of metallic liquids, the observed value for C is of the order of 10^2; this is as it should be, for in metallic liquids the conductivity is due to electrons and the hole theory is inapplicable.

Substance	Temperature (T°K.)	Thermal conductivity, χ (watts/cm. deg.)	Specific heat, S (joule/gm.)	Surface tension, σ (dyne/gm.)	C
Mercury	273	8360	0·14	466	158

Deformation of Rubber-like Materials

IN a recent paper on the highly elastic deformation of polymers, Aleksandrov and Lazurkin[1] give the following expressions, first for the total deformation $D(t)$ of rubber at time t after application of a constant stress:

$$D(t) = D_0 + D\infty\ (1-e^{-t/\tau}), \quad . \quad . \quad . \quad . \quad (1)$$

and second, for the amplitude D of deformation under a harmonic stress:

$$D = D_0 + \frac{D_\infty}{1 + i\omega\tau}; \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where D_0 is the 'ordinary elastic' component, very small compared to D_∞; D_∞ the 'highly elastic' component, obtained for $t \to \infty$ in (1) or $\omega \to 0$ in (2); ω is $2\pi \times$ the frequency of the applied stress; τ a 'relaxation time'.

It may be noticed that expressions (1) and (2) would be given by the mechanical model shown in Fig. 1, where K_0 is the stiffness of a spring corresponding to the 'ordinary (crystal) elasticity'; K_∞ one corresponding to the 'high elasticity'; R the 'damping coefficient' of a dashpot in parallel with the spring, giving rise to a viscous force proportional to the velocity. When a constant force F is applied to the system, the solution of the equation of motion gives the displacement:

$$D(t) = \frac{F}{K_0} + \frac{F}{K_\infty}(1 - e^{-tK_\infty/R}); \quad . \quad . \quad (3)$$

while for a harmonically varying force $Fe^{i\omega t}$ the steady state solution is a harmonic displacement of frequency $\omega/2\pi$ and amplitude D:

$$D = \frac{F}{K_0} + \frac{F}{K_\infty + i\omega R} \quad . \quad . \quad . \quad . \quad . \quad (4)$$

(3) and (4) reduce respectively to (1) and (2) on writing $D_0 = F/K_0$; $D_\infty = F/K_\infty$; $\tau = R/K_\infty$.

If one considers a rubber unit stressed, for example, in shear, it is easy to see on introducing an elastic modulus G and a 'normal viscosity coefficient' ν (cf. Kimball[2]) that the 'relaxation time' τ has the expression

$$\tau = R/K_\infty = \nu/G \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

It is of interest to compare the results of Aleksandrov and Lazurkin with those of other workers using the free or forced vibrations of tuned systems, as shown in the mechanical model of Fig. 2. The 'ordinary' elasticity was neglected by these authors ($1/K_0 = 0$); a justifiable approximation for the type of polymers and range of temperatures in their work.

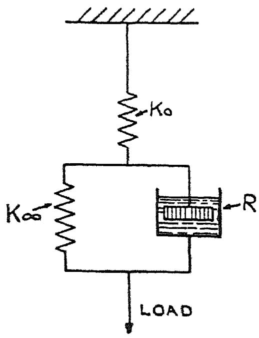

Fig. 1.

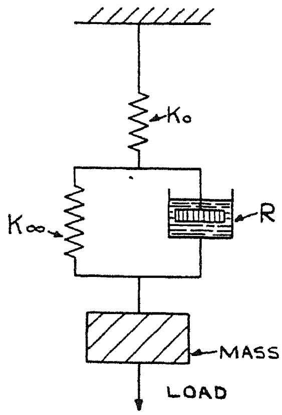

Fig. 2.

An advantage of the tuned system method is that it permits the separate determination of elastic and viscous forces. The elastic modulus is determined from the frequency of the free vibration[3], or from the frequency of resonance of the forced vibration[4,5]. The viscosity coefficient is determined from the rate of decay of the free vibration[3], or from the amplitude at resonance of the forced[4,5]. The 'relaxation time' is then determined from Equation 5: $\tau = \nu/G$. Now all the authors quoted[3,4,5] have found that G varies little, if at all, with frequency, while ν is roughly inversely proportional to frequency. This fits in better with the phenomena of elastic hysteresis connected with ordinary elastic solids (cf. ref. 2) than with the notion of a 'relaxation time' constant at a given temperature. In order to connect these results with the 'freezing up' of rubber with increased frequency observed by Aleksandrov and Lazurkin, one would expect the curve of τ versus frequency to start at low frequencies roughly in the shape of a rectangular hyperbola, but tend asymptotically with increasing frequency to a constant positive value. The determination of G and ν over a wide range of frequencies and temperatures would not only be of theoretical interest, but also of great practical value in the engineering application of rubber. One further point that is best brought out by the forced vibration method is the departure from linearity of elastic and viscous effects in rubber: it is found that the measured values of G and ν vary with the amplitude of strain.

Solubility of Basic Open Hearth Slags

A CONSIDERABLE amount of work has been done, over a number of years, regarding the phosphate solubility of basic open hearth slags. The *Proceedings of the Faraday Society* of 1920 contains "A Symposium on Basic Slags" giving much data regarding the subject of phosphate solubility.

Our investigations, commenced in 1920, employed pieces of basic finishing slag, in lump form (Fig. 1) instead of the powdered samples used in the original work. These sample pieces of slag have been subjected to extraction in 5 per cent hydrogen chloride solution, the acid solvent being changed at 24-hour intervals and analyses made on the contents of these soluble portions, these results representing the daily extraction.

This method of extracting revealed an interesting fact, namely, that when the acid extraction was complete, a practically pure silicious resdeue (Fig. 2) remained in the beaker. The residue was of similar shape and size to that of the original slag lump, but was in appearance of a porous skeleton nature.

The rate of solution of the different constituents is also informative, as shown in Fig. 3. The extraordinary feature is the residual matrix of practically pure uncombined silica (Fig. 2). The chart gives the relative solubility rates of typical slag lumps extracted by a 5 per cent hydrogen chloride solution.

Reproducible results can be obtained on various basic open hearth finishing slags, irrespective of their origin.

The above experiments led us to use a similar extraction method on transparent, glassy, amber-coloured slags extruded into the cavity at the head of large forging ingots of acid open hearth steel. The typical analysis of these slags is as follows:

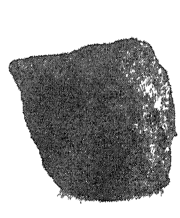

Fig. 1.

Fig. 2.

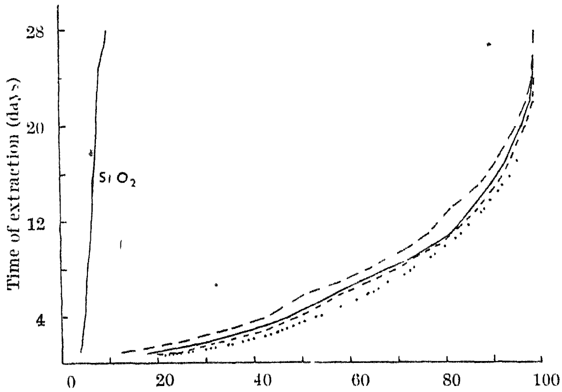

Fig. 3. SOLUBILITY OF LUMP BASIC SLAG IN 5 PER CENT HYDROGEN CHLORIDE SOLUTION.
Fe, ———— ; CaO, - - - - - ; MnO, ... ; P_2O_5, — — —.

silica, 45·51 ; ferrous oxide, 0·90 ; alumina, 23·10 ; manganese oxide, 28·52 per cent.

When extracted by warm, concentrated hydrochloric acid, these slags yield white, glossy residues of pure silica.

Further interesting phenomena were observed during an investigation dealing with hæmatite iron ores. Ordinary lump ore samples when extracted in concentrated hydrochloric acid, as above, leave a rigid porous skeleton of pure silica ; this residue has a crystalline appearance. Samples of kidney and pencil ores from the same mine, when thus extracted, leave the silica in a laminated, transparent, gelatinous form.

The information, here available, may shed some light on this very obtuse problem and be of value to future investigators.

Non-Solar Planetary Systems

IN his communication in NATURE[1] on non-solar planetary systems, Sir James Jeans writes, "Mr. Sen refers with approval to Banerji's modification of this [tidal] theory. This makes the original sun a Cepheid which had its oscillatory instability increased by the gravitational attraction of a passing star. But a passing star cannot increase the instability of a Cepheid appreciably unless it comes very near. . . . Judging from their luminosity, all Cepheids are much more massive than the sun or 61 Cygni or 70 Ophiuchi."

In my paper[2] on "The Instability of Radial Oscillations of a Variable Star and the Origin of the Solar System", I have given a theory which, I believe, satisfactorily accounts for the amount of angular momentum and energy possessed by the planets. The sun is supposed to have been originally a *part* of a Cepheid variable much heavier than the sun, which oscillated radially with small amplitude. It has been shown mathematically that the oscillations are stable only if the amplitude is so small that its square may be neglected. Instability will ensue if the amplitude is increased so that its square can no longer be neglected. The nearby passage of a star of about the mass of a Cepheid increased the amplitude of the oscillations, rendering them unstable. Matter was consequently thrown out, which condensed into the sun and the planets. If the parent Cepheid had a mass about nine times that of the sun, the sun and its planets would take away about two fifths of the Cepheid's energy. It has also been shown that the encounter need not be "very close", nor need the intruding star have an inordinately large velocity to give the requisite angular momentum to the sun and the planets and enough energy to the solar system to escape from the parent Cepheid. It appears that due to the difficulties of transit at present, Sir James Jeans has not perhaps seen my paper.

Jeans has also suggested[3] that the sun was originally big enough to include the orbit of Uranus and yet not too diffuse to hang together dynamically. There are several difficulties in such a theory which cannot be explained satisfactorily. The angular velocity imparted to the surface of the primitive sun extending up to the orbit of Uranus will presumably be of the same order as the angular orbital speed of Uranus. If the sun contracted from its enormous original size to its present dimensions, its angular velocity should increase considerably. Even granting that 98 per cent of the original angular momentum has been taken away by the planets, a little calculation will show that the sun should be rotating with at least 400 times its present angular velocity and should on that account become *distinctly* spheroidal in shape.

Moreover, with such rapid rotation, possibly the critical value for $\omega^2/2\pi\gamma\rho$ will be reached, and there will be equatorial break-up, resulting in the formation of rings of particles surrounding a central lenticular mass. Again, if the planets had taken away 98 per cent of the total angular momentum as calculated on the above theory, they should be revolving much more rapidly at present.

Another point in this theory may also be mentioned. Jeans supposes that the planets are most likely to have been formed before the sun's radius fell much below 4,000 times its present radius. It is difficult to understand what processes might have helped to bring the innermost planets to their present distances of the order of 100 times the sun's radius.

Sen has referred in his communication in NATURE[4] to the well-known Jeans-Jeffreys theory, from which it follows that planetary systems should be of "the nature of freak formations"[5]. It seems that he did not refer to Jeans's recent communication in NATURE[1], as the suggestions there are "very tentative".

APPLICATION OF GENETICS TO PLANT AND ANIMAL BREEDING

THE Genetical Society held a symposium on the "Application of Genetics to Plant and Animal Breeding" in London on April 13. The president, Dr. C. D. Darlington, in opening the meeting, said that genetics owes a debt to plant and animal breeding both for its foundation and its development. If the purpose of agriculture in the future is to be the highest production, genetics will have the opportunity of repaying this debt. The object of the symposium was to discuss whether genetics has the capacity to do so.

Mr. M. B. Crane, dealing with fruit and forest tree breeding, said that the production of new varieties, and the maintenance and efficient use of old ones, are problems within the scope of our present genetic knowledge. The first essentials for improvement are a knowledge of modern techniques and of the variation, relationship and distribution of the plants and trees within the different groups. Without this knowledge the breeder would often be working in the dark and be likely to follow some of the old traditions, such as breeding from the best for the best, often to find that this does not work.

The cost of fighting the diseases and pests of fruit, as of other crops, can be largely saved by the establishment of resistant and immune forms, so far attempted only on a small scale. Many crops are susceptible to injury by the sulphur, copper and other drugs used to combat diseases. It is known that immunity to this injury is often heritable. Advantage is likely to be obtained by the replacement of continuous vegetative propagation by sexual propagation. The devastation wrought by virus disease on the growth and yield of raspberries and strawberries, and the common freedom of seedlings from serious infection for a profitable time might be turned to account. The uniformity of healthy clonal reproduction would not be surpassed, but, in the clone, virus gives rise to great variability and decline in yield, quality and growth.

In apples and pears about a third of the varieties are triploids. This means that they have been favoured by selection. In the past we have had to depend on their spasmodic occurrence. In pears triploid families can now be raised at will, and the breeding and induction of tetraploids is likely to give new forms of outstanding value. To get the best from new polyploid fruits, new polyploid root-stocks might have to be made to fit them. In addition to old varieties, new wild stocks of useful species should be collected and established for the breeders' use, to introduce frost and disease resistance and high nutritive value and to maintain hybrid vigour and variability.

In our farm and garden crops selection and breeding have given us many improved forms which have long ago displaced most of the original wild forms from cultivation. In Great Britain, practically no such improvement has been made or even attempted with forest trees. It seems to be assumed that with est trees technique would be difficult, and selection breeding work inevitably prolonged. In the ed States and in Sweden, however, both selection reeding of forest trees have been carried out ecisive results in a short time. Selection for and quality has been effective, and important ers such as frost resistance and rapidity of growth have been combined by hybridization. The efficiency of new afforestation programmes will depend on the use made of genetics.

Prof. H. G. Champion indicated the great scope for the practical application of the genetical knowledge which can be gained about our important forest trees. He said it is exceptionally wide in Great Britain owing to the general reliance on plantations for regenerating or creating forests, and to the widespread use of exotic species. The consequences of mistakes made in selection of the stock used in any locality will carry on for at least a tree generation. Relatively little intensive research has been done on forest trees; but there is ample evidence that the majority of the factors most important to foresters both in growing their forests and in the quality and quantity of their final yield vary to an important extent with genetic constitution.

The older work has been mainly the comparison in various localities of results obtained with collections of seed made in different parts of the geographic range of the species concerned. This work has demonstrated that differences often occur so marked that on the right choice might depend outstanding success or complete failure. Such studies cover all the common species but have given particular attention to *Pinus sylvestris*. More recently, attention has been paid to controlled pollination both to ensure homogeneity and to study the results of crossing both within a species and between species. Examples of commercially important hybrids and polyploids are available, notably with Larix and Populus.

Genetical research on forest trees and the practical application of results present special difficulties as compared with similar work on other plants. These have probably been over-emphasized, but are the main cause of the relative neglect under which the subject has suffered at the hands of botanists and practical foresters. These difficulties were briefly reviewed. For research, they derive from the large size of the tree unit, the late maturation and inaccessibility of the flowering branches, and the fact that growth in crops is essential for proper assessment. In application of results, these same hindrances are involved and, furthermore, most forest trees cannot easily be multiplied vegetatively. Considerable progress has already been made in surmounting these obstacles and it is thought that many of the problems should be capable of solution; organized attack with official support is strongly to be recommended.

Prof. T. J. Jenkin explained the conflict that existed before genetic methods were applied to grass breeding. The grassland farmer wanted a permanent sward, and the seedsman selected for abundant seed; but the two are incompatible. More recent work has been directed mainly towards improvements in yield, particularly in the form of hay, and it was not at first realized that practical grass-breeding involves at least two distinct problems, of which the simpler and less important is this increased hay yield. The second, and the more important under Welsh conditions, is the production of persistent and productive strains that will stand continuous grazing over a period of years. The grasses, even apart from their heterozygosity, are not good subjects for formal genetical studies (except where defective seedlings are concerned) because they present very few characters that can be easily observed in the mature plant. The important characteristics such as growth habit, tillering capacity, persistence of the individual plant,

time of flowering, growth and productivity and so on are presumably extremely complex, and a satisfactory method of studying them is greatly needed. At the same time, the grass breeder should not completely neglect formal genetics, and particularly should a general genetical survey of plant material be made if only in order that a more definite estimate of the total heterozygosity of the various species might be made.

Dr. G. D. H. Bell pointed out that the most obvious contribution which genetics can make to the breeding of crop plants is to improve the efficiency of selection of parental material, and of the desired genotypes in mixed or hybrid populations. Many of the attributes which determine the agricultural and economic value of a crop are of a complex nature, showing the general characteristics associated with quantitative or polygenic inheritance, and improvement depends on the accurate genotypic selection of the most desirable combinations of these attributes. Therefore, although more knowledge is necessary concerning the genetics of quantitative characters in general, and of certain 'breeding characters' in particular, it is necessary to realize that the latter require careful definition and resolution in relation to their morphological and physiological components before genetic analysis is attempted.

Where crop improvement is dependent largely on hybridization, its efficiency is dependent, first, on the correct choice of the parental material, and it is essential to have knowledge concerning the breeding value of the material available, and the possibilities of combining characters which might show physiological incompatibility. This is a matter of considerable importance in any scheme of hybridization which involves a progressive synthesis of components affecting the expression of a complex character.

Accurate genetical investigation is dependent on the reasonably easy recognition of genotypes and genotypic variation. The difficulty in plant breeding which involves field selection is the assessment of the individual, or of a small progeny, when several characters are concerned and each is affected to varying degrees by the environment. Attempts have been made to develop selection indices for improving the efficiency of field selection; but there are considerable difficulties in the application of such methods to any reasonable amount of breeding material. However, it is in relation to the above considerations that any further contributions on the part of genetics to plant improvement must be considered.

Dr. K. Mather remarked that the progress of genetics has not yet led to the marked advances in plant and animal breeding which has been so confidently expected in the past. He pointed out that it will be necessary to determine which branches of genetical study are directly concerned with the problems of breeding, and deliberately to foster investigations of these kinds. They must aim primarily at increasing the precision with which the tools of the breeder—selection, adjustment of the mating system, and adjustment of population size—can be used to manipulate the heritable variation which constitutes his raw material.

The first necessity is a knowledge of the type of inheritance involved in breeding for any particular character, and this is not yet available in all cases. Where inheritance is simple, depending on major genes, genetics can already supply the information necessary for estimating the progress which might be expected, for determining how to plan the breeding programme, and for calculating its magnitude. The great majority of characters involved in breeding programmes, however, show polygenic variation, depending on many genes having small, similar and supplementary effects. Such genes determine a type of inheritance different from and more complex than that depending on major genes. Furthermore, they cannot be individually identified owing to the masking effects of one another and of non-heritable variation. Genetics has in the past offered little help in handling polygenic variation; but recent investigations are changing this situation. Methods are now available for separating and estimating, from F_2 and F_3 data, the non-heritable, fixable genetic, and unfixable genetic, parts of the variation in crosses, and so of gaining an idea of the progress which can be expected from them. The action of selection on such systems of variation is also being elucidated, as is the response of variation to changes in mating system. These advances have been made possible by the application of statistical methods developed during the past fifteen years, and further progress in this field will depend on the close co-operation of geneticists, breeders and statisticians.

Dr. Mather concluded by discussing the possibilities of building up new systems of variation through species crossing and polyploidy, and of inducing new and desirable variation by experimental means.

Turning to cattle breeding, Dr. H. P. Donald pointed out that the evolution of breeds is controlled by the isolation and size of populations, random fluctuations in gene frequency, and selection. Isolating factors at work both within and between breeds include pedigree registration, closed herds, attestation, geography and breeding objective. Within breeds, however, the rate at which breeding stock, especially bulls, are exchanged between one partially isolated group and another must reduce the effects of the isolation and prevent the growth of locally adapted types. The small size of many herds retards selection. In one breed, about 70 per cent of the herds are estimated to have fewer than twenty-five calved cows or heifers. The number of bulls in use is correspondingly small, and the result is that the herd is subject to random fluctuations in gene frequency, that the stockbreeder is obliged to purchase bulls, and finds difficulty in discriminating against unsuccessful sires. The constant process of dispersal of established herds and their replacement by new ones results in a herd-age distribution somewhat resembling the age distribution of animals themselves. There are many herds which have had opportunity to practise selection for only three or fewer generations. About 60 per cent of the herds in a sample of 475 herds in one breed of dairy cattle have been breeding pedigree animals for seventeen years or less. This immaturity of so many herds must also markedly reduce the amount of effective selection being practised within breeds.

Dr. A. Walton said the main function of the animal in farming economy is the conversion of available raw materials, unsuitable or less suitable for direct human consumption, into products whic[h] can be directly consumed. It follows from this t[hat] as techniques of production improve, not only [does] the standard of the product rise but so also do[es the] standard of nurture of the animals supplyi[ng the] product. Livestock is improved as a direct r[esult of] better nurture. Improvement might be inde[pendent]

of any change of genotype, although the expression of the genes might be considerably altered. In the past, improvements due to both nurture and genetic selection have proceeded simultaneously and it is impossible to evaluate either separately. Livestock improvement is not the simple sum of improved nurture plus genetic improvement but is more nearly expressed as the resultant of the two factors acting together. If genetic selection is applied to a heterogeneous population maintained at a constant level of nurture some improvement might result from the isolation and combination of major genes. There will be an approach to homozygosity and genetic stability, and the level of nurture will set a limit to any further improvement. If the standard of nurture of a heterozygous population is raised, there will be increased differentiation of genotypes, and selection (whether conscious or natural) will proceed more rapidly than on a lower plane but eventually the same condition of stability will be reached. By feeding animals individually and successively raising the plane of nurture, and by selecting those genotypes which respond, the breeder directs the evolution of superior strains. In the past, nutritional research and genetics have been carried out in isolation. Livestock improvement requires the combined attention of both nutritionist and geneticist.

Dr. J. M. Rendel argued that, owing to the division which exists between commercial and stud breeding in animal husbandry, attempts to improve stock are handicapped in two ways.

(1) The size of the effective breeding population is reduced to approximately 1,250 males and 30,000 females per breed in sheep, 180 males and 5,000 females in cattle, and 70 males and 1,000 females in pigs, these being the populations required to provide sires for the commercial breeders; the universal introduction of artificial insemination will reduce the size of stud populations, if the present organization is kept, to ridiculously small numbers. In such small populations the variability upon which selection depends is reduced and recombination of genes in any particular way is made more difficult; the comparatively small size of flocks and herds of sheep and cattle may account for the restricted lines along which each breed has been improved as compared to the Rhode Island Red, which, with a prewar population of twenty million, combines good table qualities with a very large egg production.

(2) There is reason to believe that if selection is carried out to produce a given character in two different environments, two different sets of genes will be selected, neither of which would produce the desired result if the environments were interchanged; thus, where stud breeders are selecting in an environment different from the one the commercial farmer will provide, they are selecting animals in a direction not best suited to the commercial breeder. The distinction, therefore, between commercial and stud breeding should go, and populations made up of whole breeds, working under uniform environmental conditions, be treated as one unit for breeding purposes.

Prof. R. A. Fisher said that the production of *élite* breeding stock is a different matter from its ssemination or its utilization. In the period of dern genetics, the traditional procedure of selective ding has been shown to be capable of great ration by the use of objective tests of perice, developed chiefly abroad. Progeny tests ere included, for they are only performance tests applied to relatives, usually daughters, of the animals selected. Unfortunately, they can only be applied to the minority, the great majority having to be eliminated on other grounds.

It should be remembered in this regard that mothers are as closely related as daughters. The only difference is that there are fewer mothers. The advantage of using daughters for performance tests depends, therefore, on their correct statistical treatment.

Recording societies do valuable work in testing performance in practical conditions of animal husbandry, but the conditions are highly variable. There is need for selective livestock improvement centres equipped to carry out tests with some experimental refinement. These could issue certificates of performance, and should be associated with selective breeding projects (Prof. Fisher personally favouring dual-purpose projects), with the central organization of recording activities, and with artificial insemination units. Artificial insemination alone, however, can do little towards livestock improvement, unless based on the use of objectively tested stock. Price is no criterion.

The genetic personnel available is so limited for any serious programme of livestock improvement that specialization will be essential. The problem of improving the objective tests so far used in respect of precision, for the two objects of (*a*) assessing the commercial value of a farm animal, and of (*b*) assessing its breeding value, is too technical and intricate to be added to the responsibilities of the livestock improvement centres. There is need of a single laboratory charged solely with the study of these tests, with the view of increasing their precision in these two respects. In addition to the published literature, it should in time be able to draw valuable data from the experience of carefully planned selective improvement projects carried out with the best available types of livestock.

For the sake of brevity, Prof. Fisher omitted reference to the very extensive, important and successful work carried out in hybrid corn programmes in the United States; as this was referred to in discussion, he added that he regards the experience gained in this field in the last twenty years as of the utmost consequence, especially to animal breeders.

In the discussion, Dr. A. E. Brandt explained that twenty years ago maize yields in the United States were no higher than those produced by the Indians before the discovery of America. Breeding improvement had no more than made up for soil deterioration; but lately a great change has taken place. From 10 million acres of maize in Iowa in 1933 the yield was 37 bushels per acre; in 1942 it was 62 bushels per acre, both without fertilizers. Two thirds of the increase was due to the use of hybrid seed produced for local conditions.

Touching this question, Dr. S. Ellerton said that breeders would sometimes maintain that a particular crop or animal has been so highly bred that further genetical improvement would be so slight and so difficult as not to be worth while. This was said of maize before the introduction of hybrid combinations of inbred lines. It has been said of cattle in the U.S.S.R. and of cereals in Great Britain. In his opinion, such apparent 'genetical limits' are merely imposed by the shortcomings of current breeding methods and would prove to be false, as was clearly so in maize. In the case of wheat he had some evidence. In 1943 he tested forty-two F_1's involving

he b(ıt varieties against their parents ınd e ,verage ıncrease in the hybrids of 10 pe 'ɔer of ears per plant and 4·6 per 'ent i ɔrain per ear, a total increase of 5 pe1 l of grain. Some individual crosses wou… ,how more heterosis than others, so that this strongly suggested that wheat could be bred for British conditions with yield increases of 20 per cent at least.

Dr. J. S. Huxley and others stressed the need for physiological and genetical examination of practical breeders' data, which are now available.

Prof. J. B. S. Haldane pointed out the importance of natural selection in domestic plants and animals and of undesirable selection for high seed number, or for longevity; the fallacy of assuming that in-breeding necessarily leads to homozygosis; and the danger of standardized clonal reproduction leading to epidemics.

Mr. W. J. C. Lawrence said that ultimate progress in plant breeding would often depend on the selection for efficiency of specific nutrient intake, for rich soils as well as for poor unbalanced ones. In this regard Dr. G. D. H. Bell discussed the need for combined manurial and variety trials for selection under local and good conditions.

Dr. F. Yates directed attention to the importance of testing new varieties of agricultural crops under a wide range of environmental conditions. Varieties might vary considerably in their reactions to different weather conditions, different soil types and different nutrient supplies in the shape of fertilizers. Thus, for example, one of the biggest factors limiting the yield of cereals in Great Britain is their inability to stand up to high levels of nitrogenous manuring without lodging. Modern developments in the technique of experimental design, in particular the development of factorial experiments, which enable several factors to be tested simultaneously (for example, varieties and different fertilizer components), provided the necessary machinery by which such tests can be efficiently made. It is equally important to carry out the tests at a number of different centres and over a number of years, so as to obtain adequate variation in weather and soil conditions. Any experimental programme of this type necessarily involves a large number of co-ordinated experiments. The organization required for the efficient execution of such experiments has not yet been fully developed, but there is now good prospect of radical improvement in this respect. It is of the utmost importance that the plant-breeding interests should be adequately represented, and should lend their full support to the development of such a co-ordinated programme.

Dr. Darlington, summing up, said that the papers showed an important contrast in treatment between two levels of breeding practice. On one hand there is the situation where common sense alone will sufficiently indicate the breeding programme in its initial stages. This is particularly true in undeveloped conditions and those where negative selection has been practised. Examples have been described in grasses and forest trees where commercial practice favours quantity of seed rather than quality of fodder or timber, and in cattle-breeding when the breed society, founded to improve cattle, has become organized to prevent improvement, a condition which will obviously be broken down by the spread of artificial insemination. No more economical or fruitful programme of genetical research in cattle-breeding could be suggested than the long-neglected survey of actual breeding practice and performance in Great Britain to-day, the outlines of which were indicated by several speakers. At the other extreme is the situation of the highly developed breeds of poultry and varieties of cereals where maintenance and, still more, improvement demand a skilful combination of elaborate techniques. The statistician is necessary for design and for interpretation, the cytologist for exploration and creation, the geneticist for planning and direction. The discussion was chiefly useful in showing what the different levels of organization are and where each is required.

TUBERCULOSIS AND PULMONARY DISEASE

A RECENT issue of the *British Medical Bulletin* (2, No. 2; 1944) is devoted to pulmonary disease. It also contains two new features: one consists of notes from medical publications which are not classified as journals and the other lists the titles and authors of papers in medical journals published in Great Britain and Northern Ireland.

Dr. P. M. D'Arcy Hart, in a special article on the medical and social aspects of pulmonary disease, deals with tuberculosis and industrial diseases of the lungs. The Committee on Tuberculosis in War-time, set up by the Medical Research Council, reported that the social background of tuberculosis is of primary importance and emphasizes the part played by war-time conditions in the rise of mortality due to tuberculosis which has occurred between 1939 and 1941. Blackout, over-crowding, the movement of populations, destruction of homes by bombing, and the entry into industry of people who are not accustomed to its conditions and fatigue are all factors contributing to this rise. Nutritional deficiency is probably less important in this War than it was during 1914–18, because of our efficient national food policy. But working conditions should be carefully watched, especially those of young adults, who are especially susceptible to tuberculosis. The Committee recommends (1) routine mass radiography and advocates the miniature method pioneered by Abreu in Brazil, priority being given to young adults such as factory employees, medical students, nurses, merchant seamen; (2) special money grants to sufferers for at least a year to enable them to leave work, maintain their own standard of living and that of their families and to undergo treatment; (3) rehabilitation of convalescents and, if possible, their gradual return to work.

The Ministry of Health has already instituted the main recommendations of this report. War-time restrictions, Dr. Hart says, have limited the manufacture and issue of miniature radiography sets, but about half a dozen local authorities have received and are using them, and field trials are being carried out with them by a team appointed by the Medical Research Council. It is hard to understand why the manufacture of these sets should not be a first priority. The Ministry of Health's scheme of financial help is in general operation already. The general policy is one of continued watchfulness and avoidance of complacency which everyone will commend.

The Medical Rese⌐rch Council Committee on

Industrial Pulmonary Disease has studied the problem of silicosis in South Wales miners and also the environment of these workers. Dr. D'Arcy Hart summarizes the resultant additions to our knowledge of this problem and the Committee's recommendations. Readers interested in other work being done to increase the safety of the mines will find useful the Ministry of Fuel and Power's annual report for 1942 of the Safety in Mines Research Board (London: H.M. Stationery Office, 1943. 1*s.* net), which deals with work on coal-dust and fire-damp explosions, mining explosives, falls of ground, electrical researches and kindred problems.

In the same issue of the *British Medical Bulletin* Mr. R. C. Brock writes a valuable article on the present position of thoracic surgery. The advances in this field in recent years have been remarkable, and the surgical treatment of tuberculosis has an important place among them. Mr. Brock names X-rays and anæsthesia as the twin pillars of thoracic surgery, which requires of the surgeon such a wide knowledge of the anatomy and physiology of the chest as well as his essential pathological and medical experience. The anæsthetist has the especially difficult job of maintaining respiration and the circulation of the blood during operations on the very organs which maintain these essential functions. Mr. Brock thinks that, during the next ten years, we shall see advances in the surgery of the heart and œsophagus as great as those which have occurred in thoracic surgery during the past ten years. A good idea of the quality of the anatomical research on which thoracic medicine and surgery are based is given by the succeeding illustrated article on the anatomy of the bronchi by Dr. A. F. Foster-Carter. Excellent bibliographies add to the value of all these articles. They are supplemented by reviews of selected articles on pulmonary anatomy, surgery and disease, and on further papers on tuberculosis in children and on the statistical and social aspects of this outstanding scourge of our civilization.

The results of further important work on various aspects of tuberculosis have been published in *The Lancet* and the *British Medical Journal* during recent months and we know, from reports on the health of the occupied countries, how important a factor tuberculosis will be in the immense task of reconstruction after the War. A correspondent of *The Lancet* (Feb. 12, 1944, p. 225), taking his information from French underground medical papers, states that tuberculosis has increased in that country by at least 20–30 per cent. French medical men, moved to horror by the ever-increasing number of French workers deported to Germany who return with tuberculosis, are unable to save their lives because the necessary diets and drugs are not available. They are trying to sabotage the deportations by ordering long rest-cures, laboratory investigations, consultations with absent specialists and similar means. The discussion on nutrition in enemy-occupied Europe at the meeting of the Royal Society of Medicine on November 23, 1943 (*The Lancet*, Dec. 4, 1943, p. 703, and *Proc. Roy. Soc. Med.*, **5**, 37, Jan. 1944, p. 113) reveals a similar grave situation in Greece, Jugo-Slavia and Belgium. In the U.S.S.R. the problem is being tackled partly by village settlements similar to the English settlements at Papworth and Preston Hall, but the Russians appear to be concentrating on large-scale rehabilitation in and around the normal sites of industry (*Brit. Med. J.*, Nov. 20, 1943, p. 652).

G. Lapage.

SCIENCE CLASS CINÉ-FIL

A PARAGRAPH in the New of NATURE of November referred to a ciné-film showing th man move ment Dr. Quintin Moore, Mr. Thos. Smith Wylie and Mr. Frank G. Conway, of the Royal Technica College, Glasgow, have given the following particula regarding the method and apparatus.

Microscopical Unit. Through the courtesy of th Royal Technical College, Glasgo d the u of a 'Siedentopf' Cardioid Ult croscope (man factured by Carl Zeiss) toge r with associat apparatus.

The source of light was a 15-amp. carbon arc wi a horizontally positioned positive carbon. A converg ing lens projected the light as a parallel beam. Th light passed through a cooling chamber containing slightly acidulated 20 per cent ferrous ammonium sulphate solution, then directly to the 'Cardioid Condenser', which was fitted into the sleeve of th Abbe illuminator of the microscope. The top of th condenser was connected to the object slide by a layer of distilled water.

A 1 mm. thick quartz slide and quartz cove formed a chamber which was mounted in a meta holder and held firmly against the stage of th microscope. This quartz chamber resembles that o a hæmocytometer slide without engraved ruling; but the depth is considerably less, only 2–4 μ deep. A colloidal solution of Carey Lea's silver, suitably diluted, was placed on the centre of the object slid and excess solution overflowed into the surrounding channel. The dimensions of the colloidal silve particles were of the order of 50 mμ.

By careful adjustment and focusing, the oblique light from the condenser was made to illuminate completely the thin stratum of colloidal solution in th chamber. None of this oblique light can enter th microscope directly, due to the high numerical aper ture of the objective. The light which does enter i scattered from the surfaces of the colloidal particle and it passes into the following microscopical com bination: an apochromatic glycerine immersio objective adapted for use with the thick quart ove and of magnification 58, focal length 3 mm., an numerical aperture 0·85. The objective, carried by centring nosepiece, was used in conjunction with compensated focusing eyepiece, and the combinati gave a magnification of 1,160 diameters.

Photographic Unit. This consisted of a Bell-How 16 mm. camera fitted with a f 1·5 lens of 1 inch fo length.

The camera was mounted on a heavy base carefully set up so that the lens combinations o microscope and camera were in accurate co alignment. The camera lens set to infinity an full aperture was placed in a ground glass foc mount, which in turn was clamped to the eye of the microscope. Through this combination microscope was focused. The lens was then repla in the camera, maintaining the same relative positio of lens and eyepiece.

Kodak Super XX reversal panchromatic film w used with a camera frame speed of 4 per sec., givi an exposure of approximately ⅛ sec. per frame. N filters were used.

Excellent darkground effects were obtained wi the above equipment provided the requisite care w

CONTROL OF ST. JOHN'S WORT IN AUSTRALIA*

By Dr. A. D. IMMS, F.R.S.

FIVE speci... ... John's wort (Hypericum) occur in Australia— ... inly in Victoria and New South ...ales. These species are *H. perforatum* L., *H. ...drosæmum* L., *H. calycium* L., *H. gramineum* ...orst. and *H. japonicum* Thunb. The first-named ... by far the most widespread and the chief pest. ...etween 250,000 and 400,000 acres of land in Victoria ...nd very large areas in New South Wales are in...ested with *H. perforatum*, and it also occurs in South ...ustralia, Tasmania and Western Australia. The ...pecies was introduced in 1870 in Victoria, and since ... occurs chiefly in hill and plateau country it is one ...f the most injurious of Australian weeds. Growing ...hickly, it eliminates all low-growing vegetation ...cluding pasture grasses, and some of the areas ...overed by the weed have had to be abandoned. ... is, furthermore, poisonous to stock.

Several methods of controlling *H. perforatum* have ...een adopted in Australia and some success has been ...hieved by the application of common salt at the ...te of ten, or more, tons to the acre. This treatment, ...owever, is too expensive for general use although ... is employed in Victoria to keep the roadsides free ...om the weed. The possibility of its repression by ...sects was first taken into account in 1917, and cer...in species of Hypericum-feeding insects were intro...ced in succeeding years from England. These were ...tain beetles of the family Chrysomelidæ—the ...ecies *Chrysolina varians* Schell., *C. brunsvicensis* ...ow. and *C. hyperici* Forst., all of which are leaf-...ders. The Geometrid moths *Anaitis efformata* ...en. and *A. plagiata* L., the larvæ of which feed ... the foliage of Hypericum, were also introduced ... England. None of these appeared to become ...bli... and the primary cause of the failure of ...st of them appeared to be climatic.

...ttention was then directed to Hypericum insects ...outhern France, where field observations showed ... a high degree of control is achieved in particular ...es by the Buprestid beetle *Agrilus hyperici* Creutz. ... the Chrysomelid beetle *Chrysolina gemellata* ...si. Supplies of both these species were shipped ...ralia in 1939 and 1940. The species *Chrysolina* ... disappeared for some years after its libera... ...ut has since been found in large numbers and ... firmly established in many areas.

...e of the other species of insects introduced ... England has apparently become established. ... *C. hyperici* now occurs in many localities, as ...t only occupies a mere fraction of the total ...ericum area of Australia. *C. gemellata* became ... readily established and spread and the *Agrilus* ...*erici* gives great promise and is increasing rapidly ...everal of the areas where its original liberation ... place in 1939 and 1940. At present, however, ...area actually covered by these last two species is even smaller than that covered by *C. hyperici*. There is every prospect that the three species named will eventually occur in all the St. John's wort areas. Their present limited distribution is naturally to be expected because they have only been introduced during a brief period. The retrogression of the weed where *C. hyperici* is numerous and the continuous increase in the numbers of this insect, together with the ease with which the other species (*C. gemellata* and *A. hyperici*) have become established, give ground for confidence that a useful degree of control of the weed will, in time, be achieved.

...he Entomological Control of St. John's Wort (*Hypericum per-...m* L.) by Frank Wilson. Bull. No. 169 Council for Scientific ... ndustrial Research (Melbourne, 1943).

STRUCTURE, FUNCTION AND SYNTHESIS OF POLYSACCHARIDES*

A NEW chemical synthesis of cellobiose by a simple and direct method has been accomplished by Stacey and Gilbert. The structure of the repeating unit in cellulose is therefore well established, and the microbiological synthesis of the polysaccharide was achieved by Hibbert. Starch, another functional material of the plant, is recognizable as two structural types of polysaccharide: amylose giving the deep blue coloration with iodine and representing about 25 per cent of natural starch, and amylopectin, the remaining 75 per cent, giving a reddish-blue colour. Amylose, synthesized both by plant and muscle phosphorylase, is represented as a continuous chain of maltose units and this is completely hydrolysed to maltose by β-amylase. Amylopectin is also composed of maltose units in shorter chains which are united as a laminated or branched-chain structure, and this is hydrolysed in stages to maltose and various dextrins. The factor responsible for the synthesis of amylopectin has not yet been isolated, but attempts have been made in this direction. Products related to amylopectin have been obtained by Dr. Peat, but their identity is not yet established.

Many of the specific and somatic bacterial polysaccharides contain amino-glucose and uronic acids as constituent units. The constitutional relationship of these polysaccharides is only partly revealed, although some synthetic analogues which are bioses are seen also to have antigenic properties. Structurally related to these are the polysaccharides produced by non-pathogenic organisms such as Rhizobia; and the plant gums which also contain uronic acid groups.

Heparin, the blood anti-coagulant factor of liver, contains glucosamine and glucuronic acid units together with acetyl and sulphate residues. The chondroitin of cartilage is similar in the composition of its individual units except that galactosamine (or talosamine) replaces glucosamine.

The synthesis of the levans by enzymes has been frequently reported; their constitution is now established, as is also that of the dextrans from *Penicillium luteum* and *Leuconostoc dextranicum*. These are 1 : 6-glucopyranose polymers.

B. welchii, the gas gangrene organism, is convertible into a Gram-negative form by sodium cholate ex-traction. The Gram-positive character can be... stored by combination with the magnesium ... ribonucleic acid. The constitution of both ... and desoxy-ribonucleic acid is partly reveal... recognition of ribo- and desoxyribofuran... the mode of combination of which, wheth... or linked units, is not yet known.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT PHYSICIST in the Physics Department—The Secretary, Royal Cancer Hospital (Free), Fulham Road, London, S.W.3 (July 1).

CHEMICAL ENGINEER for Aluminium Powder and Paste Works (location, Middlesex)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2149XA) (July 1).

TWO MECHANICAL ENGINEERS with good technical and practical experience in Heavy Engineering (Reference No. C.2155XA), and a MECHANICAL ENGINEER with good technical and practical experience in Heavy Engineering plus ability to act as Assistant to Responsible Executive (Reference No. C.1994XA)—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting the appropriate No.) (July 5).

ASSISTANT MECHANICAL ENGINEERS for the Tanganyika Government Railways—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.2170A) (July 5).

CHIEF ENGINEER, Port of Basrah—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.756A) (July 5).

ASSISTANT TECHNICAL OFFICER by the Agricultural Lime Department of the Ministry of Agriculture and Fisheries—The Ministry of Labour and National Service, Room 432, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. O.N.F.1808A) (July 8).

LECTURER OR SENIOR LECTURER IN GEOGRAPHY, and an ASSISTANT LECTURER IN GEOGRAPHY—The Registrar, The University, Manchester 13 (July 10).

LECTURER (temporary) IN MINING, a LECTURER (temporary) IN MINERAL DRESSING, and a LECTURER (temporary) IN ENGINEERING—The Professor of Mining, Royal School of Mines, Prince Consort Road, London, S.W.7 (July 15).

DIRECTOR OF THE OTAGO SCHOOL OF MINES (University of Otago)—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (July 21).

JOHN RANKIN CHAIR OF GEOGRAPHY—The Registrar, The University, Liverpool (July 31).

W. H. COLLINS PROFESSORSHIP OF HUMAN AND COMPARATIVE PATHOLOGY—The Secretary, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2 (July 31).

SENIOR LECTURESHIP IN THE DEPARTMENT OF METALLURGY of the University of the Witwatersrand—Dr. W. Cullen, 4 Broad Street ..., London, E.C.2 (July 31).

...MATING AND COSTING SURVEYOR OR ENGINEER by small but ...blished firm of Civil Engineering Contractors, E. London ... Ministry of Labour and National Service, Appointments ..., Sardinia Street, London, W.C.2 (quoting Reference ...).

...AL ENGINEER by Liverpool firm manufacturing textile ...mical processes—The Ministry of Labour and National ...ointments Office, Cotton Exchange Buildings, Liverpool 3 ...rence No. A.O.128).

...THE ROYAL INSTITUTE OF CHEMISTRY—Prof. A. ... Royal Institute of Chemistry, 30 Russell Square,
